A8502

## Wide Input Voltage Range, High Efficiency Fault Tolerant LED Driver

## FEATURES AND BENEFITS

- AEC-Q100 qualified
- Wide input voltage range of 5 to 40 V for start/stop, cold crank and load dump requirements
- Fully integrated LED current sinks and boost converter with 60 V DMOS
- Sync function to synchronize boost converter switching frequency up to 2.3 MHz , allowing operation above the AM band
- Excellent input voltage transient response
- Single resistor primary OVP minimizes $\mathrm{V}_{\text {OUT }}$ leakage
- Internal secondary OVP for redundant protection
- LED current of 120 mA per channel
- Drives up to 12 series LEDs in 2 parallel strings
- $0.7 \%$ to $0.8 \%$ LED to LED matching accuracy
- PWM and analog dimming inputs
- 5000:1 PWM dimming at 200 Hz
- Provides driver for optional external PMOS input disconnect switch
- Extensive protection against:
- Shorted boost switch or inductor
- Shorted FSET or ISET resistor
- Shorted output
- Open or shorted LED pin
- Open boost Schottky
- Overtemperature (OTP)

## PACKAGE:

16-pin TSSOP with exposed thermal pad (suffix LP)

Not to scale

## DESCRIPTION

The A8502 is a multi-output white LED driver for small-size LCD backlighting. It integrates a current-mode boost converter with internal power switch and two current sinks. The boost converter can drive up to 24 LEDs, 12 LEDs per string, at 120 mA . The LED sinks can be paralleled together to achieve even higher LED currents, up to 240 mA . The A8502 can operate with a single power supply, from 5 to 40 V , which allows the part to withstand load dump conditions encountered in automotive systems.

If required, the A8502 can drive an external P-FET to disconnect the input supply from the system in the event of a fault. The A8502 provides protection against output short and overvoltage, open or shorted diode, open or shorted LED pin, shorted boost switch or inductor, shorted FSET or ISET resistor, and IC overtemperature. A dual level cycle-by-cycle current limit function provides soft start and protects the internal current switch against high current overloads.

The A8502 has a synchronization pin that allows its switching frequencies to be synchronized in the range of 260 kHz to 2.3 MHz. The high switching frequency allows the A8502 to operate above the AM radio band.
Continued on the next page...

## APPLICATIONS:

LCD backlighting or LED lighting for:

- Automotive infotainment
- Automotive cluster
- Automotive center stack

Figure 1: Application with VIN to ground short protection, using optional P-MOSFET sensing

## DESCRIPTION (continued)

The A8502 is provided in a 16-pin TSSOP package (suffix LP) with an exposed pad for enhanced thermal dissipation. It is lead $(\mathrm{Pb})$ free, with $100 \%$ matte tin lead frame plating.

## SELECTION GUIDE

| Part Number | Packing $^{*}$ |
| :---: | :---: |
| A8502KLPTR-T | 4000 pieces per 13-in. reel |

*Contact Allegro ${ }^{\text {TM }}$ for additional packing options

## ABSOLUTE MAXIMUM RATINGS*

| Characteristic | Symbol | Notes | Rating | Unit |
| :--- | :---: | :--- | :---: | :---: |
| LEDx Pins |  |  | -0.3 to 55 | V |
| OVP Pin |  |  | -0.3 to 60 | V |
| VIN, VSENSE, GATE Pins |  | VSENSE and GATE pins should not exceed $\mathrm{V}_{\text {IN }}$ <br> by more than 0.4 V | -0.3 to 40 | V |
|  | Continuous | -0.6 to 62 | V |  |
|  | t < 50 ns | -1.0 | V |  |
| FAULT Pin |  |  | -0.3 to 40 | V |
| ISET, FSET, APWM, COMP Pins |  |  | -0.3 to 5.5 | V |
| All Other Pins |  | -0.3 to 7 | V |  |
| Operating Ambient Temperature | $\mathrm{T}_{\mathrm{A}}$ | Range K | -40 to 125 | ${ }^{\circ} \mathrm{C}$ |
| Maximum Junction Temperature | $\mathrm{T}_{\mathrm{J}}(\max )$ |  | 150 | ${ }^{\circ} \mathrm{C}$ |
| Storage Temperature | $\mathrm{T}_{\text {stg }}$ |  | -55 to 150 | ${ }^{\circ} \mathrm{C}$ |

*Stresses beyond those listed in this table may cause permanent damage to the device. The Absolute Maximum ratings are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the Electrical Characteristics table is not implied. Exposure to Absolute Maximum-rated conditions for extended periods may affect device reliability.

## Wide Input Voltage Range, High Efficiency Fault Tolerant LED Driver

Temperature ( ${ }^{\circ} \mathrm{C}$ )

## FUNCTIONAL DESCRIPTION

The A8502 incorporates a current-mode boost controller with internal DMOS switch, and two LED current sinks. It can be used to drive two LED strings of up to 12 white LEDs in series, with current up to 120 mA per string. For optimal efficiency, the output of the boost stage is adaptively adjusted to the minimum voltage required to power both LED strings. This is expressed by the following equation:

$$
\begin{equation*}
V_{\mathrm{OUT}}=\max \left(V_{\mathrm{LED} 1}, V_{\mathrm{LED} 2}\right)+V_{\mathrm{REG}} \tag{1}
\end{equation*}
$$

where
$\mathrm{V}_{\text {LEDx }}$ is the voltage drop across LED strings 1 and 2, and
$\mathrm{V}_{\mathrm{REG}}$ is the regulation voltage of the LED current sinks (typically 0.72 V at the maximum LED current).

## Enabling the IC

The IC turns on when a logic high signal is applied on the PWM/EN pin with a minimum duration of $\mathrm{t}_{\mathrm{PWMH}}$ for the first clock cycle, and the input voltage present on the VIN pin is greater than the 4.35 V necessary to clear the UVLO ( $\mathrm{V}_{\text {UVLOrise }}$ ) threshold. The power-up sequence is shown in Figure 2. Before the LEDs are enabled, the A8502 driver goes through a system check to determine if there are any possible fault conditions that might prevent the system from functioning correctly. Also, if the FSET/SYNC pin is pulled low, the IC will not power-up. More information on the FSET/SYNC pin can be found in the Sync section of this datasheet.

## Powering up: LED pin short-to-ground check

The VIN pin has a UVLO function that prevents the A8502 from powering-up until the UVLO threshold is reached. After the VIN pin goes above UVLO, and a high signal is present on the PWM/EN pin, the IC proceeds to power-up. As shown in Figure 3, at this point the A8502 enables the disconnect switch and checks if any LEDx pins are shorted to ground and/or are not used.

The LED detect phase starts when the GATE voltage of the disconnect switch is equal to $\mathrm{V}_{\text {IN }}-4.5 \mathrm{~V}$. After the voltage threshold on the LEDx pins exceeds 120 mV , a delay of between 3000 and 4000 clock cycles is used to determine the status of the pins. Thus, the LED detection duration varies with the switching

Figure 2: Power-up diagram; shows VDD (ch1, 2 V/div.), FSET/SYNC (ch2, $1 \mathrm{~V} / \mathrm{div}$.), ISET (ch3, $1 \mathrm{~V} / \mathrm{div}$. ), and PWM/EN (ch4, $2 \mathrm{~V} /$ div.) pins, time $=200 \mu \mathrm{~s} / \mathrm{div}$.

Figure 3: Power-up diagram; shows the relationship of an LEDx pin with respect to the gate voltage of the disconnect switch (if used) during the LED detect phase, as well as the duration of the LED detect phase for a switching frequency of 2 MHz ; shows GATE (ch1, $5 \mathrm{~V} /$ div.), LED (ch2, $500 \mathrm{mV} / \mathrm{div}$.$) , ISET (ch3, 1 \mathrm{~V} /$ div.), and PWM/EN (ch4, $5 \mathrm{~V} / \mathrm{div}$.) pins, time $=500 \mu \mathrm{~s} / \mathrm{div}$.

## Wide Input Voltage Range, High Efficiency Fault Tolerant LED Driver

frequency, as shown in the following table:

| Switching Frequency <br> $(\mathbf{M H z})$ | Detection Time <br> $(\mathrm{ms})$ |
| :---: | :---: |
| 2 | 1.5 to 2 |
| 1 | 3 to 4 |
| 0.800 | 3.75 to 5 |
| 0.600 | 5 to 6.7 |

The LED pin detection voltage thresholds are as follows:

| LED Pin Voltage | LED Pin Status | Action |
| :---: | :---: | :---: |
| $<70 \mathrm{mV}$ | Short-to-ground | Power-up is halted |
| 150 mV | Not used | LED removed from operation |
| 325 mV | LED pin in use | None |

All unused pins should be connected with a $1.54 \mathrm{k} \Omega$ resistor to ground, as shown in Figure 5. The unused pin, with the pull-down resistor, will be taken out of regulation at this point and will not contribute to the boost regulation loop.

Figure 4B: Example with LED2 pin not being used; the detect voltage is about 150 mV ; shows LED1 (ch1, $500 \mathrm{mV} / \mathrm{div}$.), LED2 (ch2, $500 \mathrm{mV} / \mathrm{div}$.), ISET (ch3, $1 \mathrm{~V} /$ div.), and PWM/EN (ch4, $5 \mathrm{~V} / \mathrm{div}$.) pins, time $=500 \mu \mathrm{~s} / \mathrm{div}$.

Figure 4C: Example with one LED shorted to ground. The IC will not proceed with power-up until the shorted LED pin is released, at which point the LED is checked to see if it is being used; shows LED1 (ch1, $500 \mathrm{mV} / \mathrm{div}$.), LED2 (ch2, $500 \mathrm{mV} / \mathrm{div}$.), ISET (ch3, $1 \mathrm{~V} / \mathrm{div}$. ), and PWM/EN (ch4, $5 \mathrm{~V} / \mathrm{div}$.) pins, time $=1 \mathrm{~ms} / \mathrm{div}$.

## Wide Input Voltage Range, High Efficiency Fault Tolerant LED Driver

If a LEDx pin is shorted to ground the A8502 will not proceed with soft start until the short is removed from the LEDx pin. This prevents the A8502 from powering-up and putting an uncontrolled amount of current through the LEDs.

## Soft start function

During soft start the LEDx pins are set to sink ( $\mathrm{I}_{\text {LEDSS }}$ ) and the boost switch current is reduced to the $\mathrm{I}_{\text {SWSS(LIM) }}$ level to limit the inrush current generated by charging the output capacitors. When the converter senses that there is enough voltage on the LEDx pins the converter proceeds to increase the LED current to the preset regulation current and the boost switch current limit is switched to the $\mathrm{I}_{\mathrm{SW}(\mathrm{LIM})}$ level to allow the A8502 to deliver the necessary output power to the LEDs. This is shown in Figure 6.

## Frequency selection

The switching frequency on the boost regulator is set by the resistor connected to the FSET/SYNC pin. The switching frequency can be can be anywhere from 200 kHz to 2.3 MHz . Figure 7 shows the typical switching frequency for different resistor values. The relationship between FSET resistance and the typical switching frequency is given as:

$$
f_{S W}=\frac{k}{\left(R_{F S E T}+R_{I N T}\right)}
$$

where $\mathrm{f}_{\text {SW }}$ is in $\mathrm{MHz}, \mathrm{R}_{\text {FSET }}$ is in $\mathrm{k} \Omega, \mathrm{k}=20.9$, and $\mathrm{R}_{\text {INT }}=$ $0.6 \mathrm{k} \Omega$ (internal resistance of FSET pin).

In case during operation a fault occurs that will increase the switching frequency, the FSET/SYNC pin is clamped to a maximum switching frequency of no more than 3.5 MHz . If the FSET/SYNC pin is shorted to GND the part will shut down. For more details see the Fault Mode table later in this datasheet.

Figure 5: Channel select setup: (left) using only channel LED1, (right) using both channels.

Figure 6: Startup diagram showing the input current, output voltage, and output current; shows $\mathrm{I}_{\text {OUT }}$ (ch1, $200 \mathrm{~mA} / \mathrm{div}$.), $\mathrm{I}_{\mathrm{IN}}\left(\mathrm{ch} 2,1 \mathrm{~A} / \mathrm{div}\right.$.), $\mathrm{V}_{\text {OUT }}$ (ch3, $20 \mathrm{~V} / \mathrm{div}$.), and PWM/EN (ch4, $5 \mathrm{~V} / \mathrm{div}$.$) , time =1 \mathrm{~ms} / \mathrm{div}$.

Figure 7: Typical Switching Frequency versus value of $\mathrm{R}_{\text {FSET }}$ resistor.

## Wide Input Voltage Range, High Efficiency Fault Tolerant LED Driver

## Sync

The A8502 can also be synchronized using an external clock on the FSET/SYNC pin. Figure 8 shows the correspondence of a sync signal and the FSET/SYNC pin, and Figure 9 shows the result when a sync signal is detected: the LED current does not show any variation while the frequency changeover occurs. At power-up if the FSET/SYNC pin is held low, the IC will not power-up. Only when the FSET/SYNC pin is tri-stated to allow the pin to rise, to about 1 V , or when a synchronization clock is detected, will the A8502 try to power-up.
The basic requirement of the sync signal is 150 ns minimum ontime and 150 ns minimum off time, as indicated by the specifications for $t_{\text {PWSYNCON }}$ and $t_{\text {PWSYNCOFF }}$. Figure 10 shows the timing for a synchronization clock into the A8502 at 2.2 MHz . Thus any pulse with a duty cycle of $33 \%$ to $66 \%$ at 2.2 MHz can be used to synchronize the IC.
The SYNC pulse duty cycle ranges for selected switching frequencies are:

| SYNC Pulse Frequency <br> $(\mathbf{M H z})$ | Duty Cycle Range <br> $(\%)$ |
| :---: | :---: |
| 2.2 | 33 to 66 |
| 2 | 30 to 70 |
| 1 | 15 to 85 |
| 0.800 | 12 to 88 |
| 0.600 | 9 to 91 |

If during operation a sync clock is lost, the IC will revert to the preset switching frequency that is set by the resistor $\mathrm{R}_{\mathrm{FSET}}$. During this period the IC will stop switching for a maximum period of about $7 \mu$ s to allow the sync detection circuitry to switch over to the externally preset switching frequency.
If the clock is held low for more than $7 \mu$ s, the A8502 will shut

Figure 8: Diagram showing a synchronized FSET/SYNC pin and switch node; shows $\mathrm{V}_{\text {OUT }}$ (ch1, $20 \mathrm{~V} /$ div.), $\mathrm{I}_{\text {OUT }}(\mathrm{ch} 2,200 \mathrm{~mA} / \mathrm{div}$.$) , \mathrm{FSET} / \mathrm{SYNC}$ (ch3, $2 \mathrm{~V} / \mathrm{div}$.), and SW node (ch4, $20 \mathrm{~V} / \mathrm{div}$.), time $=2 \mu \mathrm{~s} / \mathrm{div}$.

Figure 9: Transition of the SW waveform when the SYNC pulse is detected. The A8502 switching at 2 MHz , applied SYNC pulse at 1 MHz ; shows $\mathrm{V}_{\text {OUT }}\left(\right.$ ch1, $20 \mathrm{~V} / \mathrm{div}$. ), $\mathrm{I}_{\text {OUT }}(\mathrm{ch} 2,200 \mathrm{~mA} / \mathrm{div}$.$) , FSET/SYNC (ch3, 2 \mathrm{~V} / \mathrm{div}$. ), and SW node (ch4, $20 \mathrm{~V} / \mathrm{div}$.), time $=5 \mu \mathrm{~s} / \mathrm{div}$.

## Wide Input Voltage Range, High Efficiency Fault Tolerant LED Driver

down. In this shutdown mode the IC will stop switching, the input disconnect switch is open, and the LEDs will stop sinking current. To shutdown the IC into low power mode, the user must disable the IC using the PWM pin, by keeping the pin low for a period of 32,750 clock cycles. If the FSET/SYNC pin is released at any time after $7 \mu \mathrm{~s}$, the A8502 will proceed to soft start.

To prevent generating a fault when the external SYNC signal is stuck at low, the circuit shown in Figure 11 can be used. When the external SYNC signal goes low, the A8502 will continue to operate normally at the switching frequency set by RFSET. No FAULT flag is generated.

Figure 10: SYNC pulse on and off time requirements.

Figure 11: Countermeasure to prevent external sync signal stuck-at-low fault

If it is necessary to switch over between internal oscillator and external sync during operation, ensure the transition takes place at least 500 ns after the previous $\mathrm{PWM}=\mathrm{H}$ rising edge. Alternatively, execute the switchover during $\mathrm{PWM}=\mathrm{L}$ only. This restriction does not apply if PWM dimming is not being used.

Figure 12: Avoid switching over between Internal Oscillator and External Sync in highlighted region

## Wide Input Voltage Range, High Efficiency Fault Tolerant LED Driver

## LED current setting and LED dimming

The maximum LED current can be up to 120 mA per channel, and is set through the ISET pin. To set the $\mathrm{I}_{\text {LED }}$ current, connect a resistor, $\mathrm{R}_{\text {ISET }}$, between this pin and ground, according to the following formula:

$$
\begin{equation*}
R_{\mathrm{ISET}}=(1.003 \times 980) / I_{\mathrm{LED}} \tag{2}
\end{equation*}
$$

where $\mathrm{I}_{\text {LED }}$ is in A and $\mathrm{R}_{\text {ISET }}$ is in $\Omega$. This sets the maximum current through the LEDs, referred to as the $100 \%$ current. Standard $\mathrm{R}_{\text {ISET }}$ values, at gain equals 980 , are as follows:

| Standard Closest R $_{\text {ISET }}$ <br> Resistor Value <br> $(\mathbf{k} \Omega)$ | LED current per LED, I <br> (mA) |
| :---: | :---: |
| 8.25 | 120 |
| 9.76 | 100 |
| 12.1 | 80 |
| 15.0 | 65 |

## PWM dimming

The LED current can be reduced from the $100 \%$ current level by PWM dimming using the PWM/EN pin. When the PWM/EN pin is pulled high, the A8502 turns on and all enabled LEDs sink $100 \%$ current. When PWM/EN is pulled low, the boost converter and LED sinks are turned off. The compensation (COMP) pin is floated, and critical internal circuits are kept active. The typical PWM dimming frequencies fall between 200 Hz and 1 kHz . Figure 13A to Figure 13D provide examples of PWM switching behavior.

Figure 13A: Typical PWM diagram showing $\mathrm{V}_{\text {OUT }}$, $\mathrm{I}_{\text {LED }}$, and COMP pin as well as the PWM signal. PWM dimming frequency is 500 Hz at $50 \%$ duty cycle; shows $\mathrm{V}_{\text {OUT }}(\mathrm{ch} 1,10 \mathrm{~V} /$ div.), COMP (ch2, $2 \mathrm{~V} / \mathrm{div}$.$) , PWM (ch3,$ $5 \mathrm{~V} / \mathrm{div}$.), and $\mathrm{I}_{\mathrm{LED}}(\mathrm{ch} 4,50 \mathrm{~mA} / \mathrm{div}$.$) , time =500 \mu \mathrm{~s} / \mathrm{div}$.

Figure 13B: Typical PWM diagram showing $\mathrm{V}_{\text {OUT }}, \mathrm{I}_{\text {LED }}$, and COMP pin as well as the PWM signal. PWM dimming frequency is 500 Hz at $1 \%$ duty cycle ; shows $\mathrm{V}_{\text {OUT }}(c h 1,10 \mathrm{~V} /$ div.), COMP (ch2, $2 \mathrm{~V} / \mathrm{div}$.$) , PWM (ch3,$ $5 \mathrm{~V} /$ div. ), and I IED $(c h 4,50 \mathrm{~mA} /$ div.), time $=500 \mu \mathrm{~s} / \mathrm{div}$.

Figure 13C: Delay from rising edge of PWM signal to LED current; shows PWM (ch1, $2 \mathrm{~V} / \mathrm{div}$.), and $\mathrm{I}_{\text {LED }}$ (ch2, $50 \mathrm{~mA} /$ div.), time $=200 \mathrm{~ns} / \mathrm{div}$.

Figure 13D: Delay from falling edge of PWM signal to LED current turn off; shows PWM (ch1, 2 V/div.), and $\mathrm{I}_{\text {LED }}$ (ch2, $50 \mathrm{~mA} / \mathrm{div}$. ), time $=200 \mathrm{~ns} / \mathrm{div}$.

## Wide Input Voltage Range, High Efficiency Fault Tolerant LED Driver

Another important feature of the A8502 is the PWM signal to LED current delay. This delay is typically less than 500 ns , which allows greater accuracy at low PWM dimming duty cycles, as shown in Figure 14.

## APWM pin

The APWM pin is used in conjunction with the ISET pin (see Figure 15). This is a digital signal pin that internally adjusts the ISET current. When this pin is not used it should be tied to ground.

The typical input signal frequency is between 20 kHz and 1 MHz .

Figure 14: Percentage Error of the LED current versus PWM duty cycle (at 200 Hz PWM frequency).

Figure 15: Simplified block diagram of the APWM and ISET circuit.

The duty cycle of this signal is inversely proportional to the percentage of current that is delivered to the LEDs (Figure 16).

To use this pin for a trim function, the user should set the maximum output current to a value higher than the required current by at least $5 \%$. The LED $\mathrm{I}_{\mathrm{SET}}$ current is then trimmed down to the appropriate value. Another consideration that also is important is the limitation of the user APWM signal duty cycle. In some cases it might be preferable to set the maximum $\mathrm{I}_{\text {SET }}$ current to be $25 \%$ to $50 \%$ higher, thus allowing the APWM signal to have duty cycles that are between $25 \%$ and $50 \%$.

Figure 16: Output current versus duty cycle; 200 kHz APWM signal.

Figure 17: Percentage Error of the LED current versus PWM duty cycle; 200 kHz APWM signal.

## Wide Input Voltage Range, High Efficiency Fault Tolerant LED Driver

As an example, a system that delivers a full LED current of 120 mA per LED would deliver 90 mA of current per LED when an APWM signal is applied with a duty cycle of $25 \%$ (Figure 18 and Figure 19).

Although the APWM dimming function has a wide frequency range, if this function is used strictly as an analog dimming

Figure 18: Diagram showing the transition of LED current from 120 mA to 90 mA , when a $25 \%$ duty cycle signal is applied to the APWM pin; PWM $=1$; shows $\mathrm{I}_{\text {LED }}$ (ch1, $50 \mathrm{~mA} /$ div.), APWM (ch2, $5 \mathrm{~V} /$ div.), and PWM/EN (ch3, 5 V/div.), time $=500 \mu \mathrm{~s} / \mathrm{div}$.
function it is recommended to use frequency ranges between 50 and 500 kHz for best accuracy. The frequency range must be considered only if the user is not using this function as a closed loop trim function. Another limitation is that the propagation delay between this APWM signal and $\mathrm{I}_{\mathrm{OUT}}$ takes several milliseconds to change the actual LED current. This effect is shown in Figure 18, Figure 19, and Figure 20.

Figure 19: Diagram showing the transition of LED current from 90 mA to 120 mA , when a $25 \%$ duty cycle signal is removed from the APWM pin. PWM $=1$; shows $\mathrm{I}_{\text {LED }}(\mathrm{ch} 1,50 \mathrm{~mA} /$ div.), APWM (ch2, $5 \mathrm{~V} /$ div.), and PWM/EN (ch3, 5 V/div.), time $=500 \mu \mathrm{~s} / \mathrm{div}$.

Figure 20: Transition of output current level when a 50\% duty cycle signal is applied to the APWM pin, in conjunction with a $50 \%$ duty cycle PWM dimming being applied to the PWM pin; shows $\mathrm{I}_{\text {OUT }}$ (ch1, $100 \mathrm{~mA} / \mathrm{div}$. ), APWM (ch2, $5 \mathrm{~V} /$ div.), and PWM/EN (ch3, $5 \mathrm{~V} / \mathrm{div}$.), time $=1 \mathrm{~ms} / \mathrm{div}$.

## Wide Input Voltage Range, High Efficiency Fault Tolerant LED Driver

## Analog dimming

The A8502 can also be dimmed by using an external DAC or another voltage source applied either directly to the ground side of the $\mathrm{R}_{\text {ISET }}$ resistor or through an external resistor to the ISET pin (see Figure 20). The limit of this type of dimming depends on the range of the ISET pin. In the case of the A8502 the limit is 40 to $125 \mu \mathrm{~A}$.

- For a single resistor (panel A of Figure 21), the ISET current is controlled by the following formula:

$$
\begin{equation*}
I_{\mathrm{SET}}=\frac{V_{\mathrm{ISET}}-V_{\mathrm{DAC}}}{R_{\mathrm{ISET}}} \tag{3}
\end{equation*}
$$

where $V_{\text {ISET }}$ is the ISET pin voltage and $V_{\text {DAC }}$ is the DAC output voltage.
When the DAC voltage is 0 V the LED current will be at its maximum. To keep the internal gain amplifier stable, the user should not decrease the current through the $\mathrm{R}_{\text {ISET }}$ resistor to less than $40 \mu \mathrm{~A}$

- For a dual-resistor configuration (panel B of Figure 21), the $\mathrm{I}_{\text {SET }}$ current is controlled by the following formula:

$$
\begin{equation*}
I_{\mathrm{SET}}=\frac{V_{\mathrm{ISET}}}{R_{\mathrm{ISET}}}-\frac{V_{\mathrm{DAC}}-V_{\mathrm{ISET}}}{R_{1}} \tag{4}
\end{equation*}
$$

(A)

Figure 21: Simplified diagrams of voltage control of ILED typical applications using a DAC to control $\mathrm{I}_{\text {LED }}$ using a single resistor (upper), and dual resistors (lower).

The advantage of this circuit is that the DAC voltage can be higher or lower, thus adjusting the LED current to a higher or lower value of the preset LED current set by the $\mathrm{R}_{\text {ISET }}$ resistor:

- $\mathrm{V}_{\text {DAC }}=1.003 \mathrm{~V}$; the output is strictly controlled by $\mathrm{R}_{\text {ISET }}$
- $\mathrm{V}_{\mathrm{DAC}}>1.003 \mathrm{~V}$; the LED current is reduced
- $\mathrm{V}_{\mathrm{DAC}}<1.003 \mathrm{~V}$; the LED current is increased

## LED short detect

Both LEDx pins are capable of handling the maximum $\mathrm{V}_{\text {OUT }}$ that the converter can deliver, thus providing protection from the LEDx pin to $\mathrm{V}_{\text {OUT }}$ in the event of a connector short.
An LEDx pin that has a voltage exceeding $V_{\text {LEDSC }}$ will be removed from operation (see Figure 22). This is to prevent the IC from dissipating too much power by having a large voltage present on an LEDx pin.
While the IC is being PWM-dimmed, the IC rechecks the disabled LED every time the PWM signal goes high, to prevent false tripping of an LED short event. This also allows some self-correction if an intermittent LED pin short to $\mathrm{V}_{\text {OUT }}$ is present.

## Overvoltage protection

The A8502 has overvoltage protection (OVP) and open Schottky diode (D1 in Figure 1) protection. The OVP protection has a

Figure 22: Example of the disabling of an LED string when the LED pin voltage is increased above 4.6 V ; shows $\mathrm{I}_{\text {OUT }}$ (ch1, $200 \mathrm{~mA} / \mathrm{div}$. ), LED1 (ch2, $5 \mathrm{~V} / \mathrm{div}$.), and PWM/EN (ch3, $5 \mathrm{~V} / \mathrm{div}$.), time $=10 \mu \mathrm{~s} / \mathrm{div}$.

## Wide Input Voltage Range, High Efficiency Fault Tolerant LED Driver

default level of 8.1 V and can be increased up to 53 V by connecting resistor $\mathrm{R}_{\mathrm{OVP}}$ between the OVP pin and $\mathrm{V}_{\text {OUT }}$. When the current into the OVP pin exceeds $199 \mu \mathrm{~A}$ (typical), the OVP comparator goes low and the boost stops switching.
The following equation can be used to determine the resistance for setting the OVP level:

$$
\begin{equation*}
R_{\mathrm{OVP}}=\left(V_{\mathrm{OUTovp}}-V_{\mathrm{OVP}(\mathrm{th})}\right) / I_{\mathrm{OVPH}} \tag{5}
\end{equation*}
$$

where:
$\mathrm{V}_{\text {OUTovp }}$ is the target overvoltage level,
$\mathrm{R}_{\mathrm{OVP}}$ is the value of the external resistor, in $\Omega$,
$\mathrm{V}_{\mathrm{OVP}(\mathrm{th})}$ is the pin OVP trip point found in the Electrical Characteristics table, and
$\mathrm{I}_{\text {OVPH }}$ is the current into the OVP pin.
There are several possibilities for why an OVP condition would be encountered during operation, the two most common being: a

Figure 23: OVP protection in an output disconnect event; shows $\mathrm{V}_{\text {OUT }}$ (ch1, $10 \mathrm{~V} / \mathrm{div}$. ), SW node (ch2, $50 \mathrm{~V} / \mathrm{div}$. ), PWM (ch3, $5 \mathrm{~V} / \mathrm{div}$.), and $\mathrm{I}_{\text {LED }}(\mathrm{ch} 4,200 \mathrm{~mA} / \mathrm{div}$. ), time $=1 \mathrm{~ms} / \mathrm{div}$.
disconnected output, and an open LED string. Examples of these are provided in Figure 23 and Figure 24.
Figure 23 illustrates when the output of the A8502 is disconnected from load during normal operation. The output voltage instantly increases up to OVP voltage level and then the boost stops switching to prevent damage to the IC. If the output is drained off, eventually the boost might start switching for a short duration until the OVP threshold is hit again.

Figure 24 displays a typical OVP event caused by an open LED string. After the OVP condition is detected, the boost stops switching, and the open LED string is removed from operation. Afterwards $\mathrm{V}_{\text {OUT }}$ is allowed to fall, and eventually the boost will resume switching and the A8502 will resume normal operation.
A8502 also has built-in secondary overvoltage protection to protect the internal switch in the event of an open diode condition. Open Schottky diode detection is implemented by detecting overvoltage on the SW pin of the device. If voltage on the SW

Figure 24: OVP protection in an open LED string event; shows $\mathrm{V}_{\text {OUT }}$ (ch1, $10 \mathrm{~V} / \mathrm{div}$.), SW node (ch2, $50 \mathrm{~V} / \mathrm{div}$.), PWM (ch3, $5 \mathrm{~V} /$ div.), and $\mathrm{I}_{\text {LED }}$ (ch4, $200 \mathrm{~mA} /$ div.), time $=500 \mu \mathrm{~s} / \mathrm{div}$.

## Wide Input Voltage Range, High Efficiency Fault Tolerant LED Driver

pin exceeds the device safe operating voltage rating, the A8502 disables and remains latched. To clear this fault, the IC must be shut down either by using the PWM/EN signal or by going below the UVLO threshold on the VIN pin. Figure 25 illustrates this. As soon as the switch node voltage (SW) exceeds 60 V , the IC shuts down. Due to small delays in the detection circuit, as well
as there being no load present, the switch node voltage will rise above the trip point voltage.
Figure 26 illustrates when the A8502 is being enabled during an open diode condition. The IC goes through all of its initial LED detection and then tries to enable the boost, at which point the open diode is detected.

Figure 25: OVP protection in an open Schottky diode event, while the IC is in normal operation; shows PWM (ch1, $5 \mathrm{~V} / \mathrm{div}$.$) , \mathrm{SW}$ node (ch2, $50 \mathrm{~V} / \mathrm{div}$.), $\mathrm{V}_{\text {OUT }}\left(\mathrm{ch} 3,20 \mathrm{~V} / \mathrm{div}\right.$.), and $\mathrm{I}_{\text {OUT }}(\mathrm{ch} 4,200 \mathrm{~mA} / \mathrm{div}$.), time $=1 \mu \mathrm{~s} / \mathrm{div}$.

Figure 26: OVP protection when the IC is enabled during an open diode condition; shows PWM (ch1, $5 \mathrm{~V} /$ div.), SW node (ch2, $50 \mathrm{~V} /$ div.), $\mathrm{V}_{\text {OUT }}$ (ch3, $10 \mathrm{~V} / \mathrm{div}$.$) , and \mathrm{I}_{\mathrm{OUT}}(\mathrm{ch} 4,200 \mathrm{~mA} / \mathrm{div}$.$) , time =500 \mu \mathrm{~s} / \mathrm{div}$.

## Wide Input Voltage Range, High Efficiency Fault Tolerant LED Driver

## Boost switch overcurrent protection

The boost switch is protected with cycle-by-cycle current limiting set at a minimum of 3.0 A . There is also a secondary current limit that is sensed on the boost switch. When detected this current limit immediately shuts down the A8502. The level of this cur-
rent limit is set above the cycle-by-cycle current limit to protect the switch from destructive currents when the boost inductor is shorted. Various boost switch overcurrent conditions are shown in Figure 27, Figure 28, and Figure 29.

Figure 28: Cycle-by-cycle current limiting; inductor current (yellow trace, $\mathrm{I}_{\mathrm{L}}$ ), note reduction in output voltage as compared to normal operation with the same configuration (Figure 24); shows SW node (ch1, $20 \mathrm{~V} /$ div.), inductor current, $\mathrm{I}_{\mathrm{L}}\left(\right.$ ch2, 1 A/div.), $\mathrm{V}_{\text {OUT }}($ ch3, $10 \mathrm{~V} /$ div.), and PWM/EN (ch4, $5 \mathrm{~V} / \mathrm{div}$.$) , time =2 \mu \mathrm{~s} / \mathrm{div}$.

Figure 29: Secondary boost switch current limit; when this limit is hit, the A8502 immediately shuts down; shows PWM/EN (ch1, $5 \mathrm{~V} / \mathrm{div}$.), $\overline{\mathrm{FAULT}}$ (ch2, $5 \mathrm{~V} /$ div.), SW node (ch3, $50 \mathrm{~V} /$ div.), and inductor current, $\mathrm{I}_{\mathrm{L}}$ (ch4, 2 A/div.), time $=100 \mathrm{~ns} /$ div.

# Wide Input Voltage Range, High Efficiency Fault Tolerant LED Driver 

## Input overcurrent protection and disconnect switch

The primary function of the input disconnect switch is to protect the system and the device from catastrophic input currents during a fault condition. The external circuit implementing the disconnect is shown in Figure 30. If the input disconnect switch is not used, the VSENSE pin must be tied to VIN and the GATE pin must be left open.

When selecting the external PMOS, check for the following parameters:

- Drain-source breakdown voltage $\mathrm{V}_{(\mathrm{BR}) \mathrm{DSS}}>-40 \mathrm{~V}$
- Gate threshold voltage (make sure it is fully conducting at $\mathrm{V}_{\mathrm{GS}}=-4 \mathrm{~V}$, and cut-off at -1 V )
- $\mathrm{R}_{\mathrm{DS}(\mathrm{on})}$ : Make sure the on-resistance is rated at $\mathrm{V}_{\mathrm{GS}}=-4.5 \mathrm{~V}$ or similar, not at -10 V ; derate it for higher temperature
The input disconnect switch has two modes of operation:
- 1X mode When the input current is between one and two times the preset current limit value, the disconnect switch enters a con-stant-current mode for a maximum duration of 10,000 cycles or 5 ms at 2 MHz . During this time, the Fault flag is set immediately and the disconnect switch goes into a linear mode of operation, in which the input current will be limited to a value approximate to the 1X current trip point level (Figure 31). If the fault corrects itself before the expiration of the timer, the Fault flag will be removed and normal operation will resume.
The user can also during this time decide whether to shut down the A8502. To immediately shut down the device, pull the FSET/ SYNC pin low for more than $7 \mu \mathrm{~s}$. After the FSET/SYNC pin has been low for a period longer than $7 \mu \mathrm{~s}$, the IC will stop switching, the input disconnect switch will open, and the LEDx pins will stop sinking current. The A8502 can be powered-down into low power mode. To do so, disable the IC by keeping the PWM/EN pin low for a period of 32,750 clock cycles. To keep the discon-

Figure 30: Typical circuit showing the implementation of the input disconnect feature.

Figure 31: Showing typical wave forms for a 3-A, 1X current limit under a fault condition; shows $\mathrm{f}_{\mathrm{SW}}=800 \mathrm{kHz}, \overline{\mathrm{FAULT}}\left(\mathrm{ch} 1,5 \mathrm{~V} / \mathrm{div}\right.$.), $\mathrm{I}_{\mathrm{IN}}(\mathrm{ch} 2,2 \mathrm{~A} /$ div.), GATE (ch3, $5 \mathrm{~V} / \mathrm{div}$.), and PWM/EN (ch4, $5 \mathrm{~V} / \mathrm{div}$.$) , time =5 \mathrm{~ms} / \mathrm{div}$.

Figure 32: 2 X mode, secondary overcurrent fault condition. $\mathrm{I}_{\mathrm{IN}}$ is the input current through the switch. The Fault flag is set at the 1 X current limit, and when the 2X current limit is reached the A8502 disables the gate of the disconnect switch (GATE); shows FAULT (ch1, $5 \mathrm{~V} / \mathrm{div}$.), GATE (ch2, $10 \mathrm{~V} /$ div.), $\mathrm{I}_{\mathrm{IN}}(\mathrm{ch} 3,2 \mathrm{~A} / \mathrm{div}$.), and PWM/EN (ch4, $5 \mathrm{~V} / \mathrm{div}$.), time $=5 \mu \mathrm{~s} / \mathrm{div}$.

## Wide Input Voltage Range, High Efficiency Fault Tolerant LED Driver

nect switch stable while the disconnect switch is in 1 X mode, use a 22 nF capacitor for $\mathrm{C}_{\mathrm{C}}$ and a $20 \Omega$ resistor for $\mathrm{R}_{\mathrm{C}}$.

- 2 X current limit If the input current level goes above 2 X of the preset current limit threshold, the A8502 will shut down in less than $3 \mu \mathrm{~s}$ regardless of user input (Figure 32). This is a latched condition. The Fault flag is also set to indicate a fault. This feature is meant to prevent catastrophic failure in the system due to inductor short to ground, switch pin short to ground, or output short to ground.

## Setting the current sense resistor

The typical threshold for the current sense circuit is 104 mV , when $R_{\text {ADJ }}$ is $0 \Omega$. This voltage can be trimmed by the $\mathrm{R}_{\text {ADJ }}$ resistor. The typical 1X trip point should be set at about 3 A , which coincides with the cycle-by-cycle current limit minimum threshold.

For example, given 3 A of input current, and the calculated maximum value of the sense resistor, $\mathrm{R}_{\mathrm{SC}}=0.033 \Omega$.

The $\mathrm{R}_{\mathrm{SC}}$ chosen is $0.03 \Omega$, a standard.
Also:

$$
\begin{equation*}
R_{\text {ADJ }}=\left(V_{\text {SENSETRIP }}-V_{\text {ADJ }}\right) / I_{\text {ADJ }} \tag{6}
\end{equation*}
$$

The trip point voltage is calculated as:

$$
\begin{aligned}
& V_{\mathrm{ADJ}}=3.0 \mathrm{~A} \times 0.03 \Omega=0.090 \mathrm{~V} \\
& R_{\mathrm{ADJ}}=(0.104-0.09 \mathrm{~V}) /(20.3 \mu \mathrm{~A})=731 \Omega
\end{aligned}
$$

## Input UVLO

When $\mathrm{V}_{\text {IN }}$ and $\mathrm{V}_{\text {SENSE }}$ rise above the $\mathrm{V}_{\text {UVLOrise }}$ threshold, the A8502 is enabled. A8502 is disabled when $\mathrm{V}_{\text {IN }}$ falls below the $\mathrm{V}_{\text {UvLOfall }}$ threshold for more than $50 \mu \mathrm{~s}$. This small delay is used to avoid shutting down because of momentary glitches in the input power supply. When $\mathrm{V}_{\text {IN }}$ falls below 4.35 V , the IC will shut down (see Figure 33).

## VDD

The VDD pin provides regulated bias supply for internal circuits. Connect the capacitor $\mathrm{C}_{\text {VDD }}$ with a value of $0.1 \mu \mathrm{~F}$ or greater to this pin. The internal LDO can deliver no more than 2 mA of current with a typical $\mathrm{V}_{\mathrm{DD}}$ of about 3.5 V , enabling this pin to serve as the pull-up voltage for the FAULT pin.

Figure 33: Shutdown showing a falling input voltage $\left(\mathrm{V}_{\mathrm{IN}}\right)$; shows $\mathrm{V}_{\mathrm{IN}}$ (ch1, $2 \mathrm{~V} / \mathrm{div}$.), $\mathrm{I}_{\mathrm{OUT}}(\mathrm{ch} 2,200 \mathrm{~mA} / \mathrm{div}),. \mathrm{V}_{\mathrm{DD}}$ (ch3, $5 \mathrm{~V} / \mathrm{div}$.), and PWM/EN (ch4, $2 \mathrm{~V} / \mathrm{div}$.), time $=5 \mathrm{~ms} / \mathrm{div}$.

Figure 34: Shutdown using the enable function, showing the 16 ms delay between the PWM/EN signal and when the VDD and GATE of the disconnect switch turns off; shows GATE (ch1, $10 \mathrm{~V} / \mathrm{div}$.), I IOUT (ch2, $200 \mathrm{~mA} /$ div.), $\mathrm{V}_{\mathrm{DD}}$ (ch3, $5 \mathrm{~V} /$ div.), and PWM/EN (ch4, $2 \mathrm{~V} / \mathrm{div}$.), time $=5 \mathrm{~ms} / \mathrm{div}$.

## Wide Input Voltage Range, High Efficiency Fault Tolerant LED Driver

## Shutdown

If the PWM/EN pin is pulled low for more than $\mathrm{t}_{\text {PWML }}(32,750$ clock cycles), the device enters shutdown mode and clears all internal fault registers. As an example, at a 2 MHz clock frequency, it will take approximately 16.3 ms to shut down the IC into the low power mode (Figure 34). When the A8502 is shut down, the IC will disable all current sources and wait until the PWM/EN signal goes high to re-enable the IC. If faster shut down is required, the FSET/SYNC pin can be used.

## Fault protection during operation

The A8502 constantly monitors the state of the system to determine if any fault conditions occur during normal operation. The
response to a triggered fault condition is summarized in the Fault Mode table.

The possible fault conditions that the device can detect are: Open LED pin, LED pin shorted to ground, shorted inductor, $\mathrm{V}_{\text {OUT }}$ short to ground, SW pin shorted to ground, ISET pin shorted to ground, and input disconnect switch source shorted to ground.
Note the following:

- Some of the protection features might not be active during startup, to prevent false triggering of fault conditions.
- Some of these faults will not be protected if the input disconnect switch is not being used. An example of this is $V_{\text {OUT }}$ short to ground.

Fault Mode Table

| Fault Name | Type | Active | Fault Flag Set | Description | Boost | Disconnect Switch | Sink <br> Driver |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Primary switch overcurrent protection (cycle-by-cycle current limit) | Auto-restart | Always | No | This fault condition is triggered by the cycle-bycycle current limit, ISW(LIM). | Off for a single cycle | On | On |
| Secondary switch current limit | Latched | Always | Yes | When the current through the boost switch exceeds secondary current SW limit (ISW(LIM2) the device immediately shuts down the disconnect switch, LED drivers, and boost. The Fault flag is set. To reenable the device, the PWM/EN pin must be pulled low for 32,750 clock cycles. | Off | Off | Off |
| Input disconnect current limit | Latched | Always | Yes | The device is immediately shut off if the voltage across the input sense resistor is 2 X the preset current value. The Fault flag is set. If the input current limit is between 1 X and 2 X , the Fault flag is set but the IC will continue to operate normally for $\mathrm{t}_{\text {GFAULT1 }}$ or until it is shut down. To re-enable the device the PWM/EN pin must be pulled low for 32,750 clock cycles. | Off | Off | Off |
| Secondary OVP | Latched | Always | Yes | Secondary overvoltage protection is used for open diode detection. When diode D1 opens, the SW pin voltage will increase until $\mathrm{V}_{\mathrm{OVP}(\mathrm{SEC})}$ is reached. This fault latches the IC. The input disconnect switch is disabled as well as the LED drivers, and the Fault flag is set. To re-enable the part the PWM pin must be pulled low for 32,750 clock cycles. | Off | Off | Off |

[^0]
## Wide Input Voltage Range, High Efficiency Fault Tolerant LED Driver

Fault Mode Table (continued)

| Fault Name | Type | Active | Fault Flag Set | Description | Boost | Disconnect Switch | Sink driver |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| LED Pin Short Protection | Auto-restart | Startup | No | This fault prevents the device from starting-up if either of the LEDx pins are shorted. The device stops soft-start from starting while either of the LEDx pins are determined to be shorted. After the short is removed, soft-start is allowed to start. | Off | On | Off |
| LED Pin open | Auto-restart | Normal Operation | No | When an LEDx pin is open the device will determine which LED pin is open by increasing the output voltage until OVP is reached. Any LED string not in regulation will be turned off. The device will then go back to normal operation by reducing the output voltage to the appropriate voltage level. | On | On | Off for open pins. On for all others. |
| ISET Short Protection | Auto-restart | Always | No | This fault occurs when the ISET current goes above $150 \%$ of the maximum current. The boost will stop switching, the disconnect switch will turn off, and the IC will disable the LED sinks until the fault is removed. When the fault is removed the IC will try to to regulate to the preset LED current. | Off | On | Off |
| FSET/SYNC Short Protection | Auto-restart | Always | Yes | Fault occurs when the FSET/SYNC current goes above $150 \%$ of maximum current, about $180 \mu \mathrm{~A}$. The boost will stop switching, the disconnect switch will turn off, and the IC will disable the LED sinks until the fault is removed. When the fault is removed the IC will try to restart with soft-start. | Off | Off | Off |
| Overvoltage Protection | Auto-restart | Always | No | Fault occurs when OVP pin exceeds $\mathrm{V}_{\text {OVP(th) }}$ threshold. The A8502 will immediately stop switching to try to reduce the output voltage. If the output voltage decreases then the A8502 will restart switching to regulate the output voltage. | Stop during OVP event. | On | On |
| LED Short Protection | Auto-restart | Always | No | Fault occurs when the LED pin voltage exceeds $\mathrm{V}_{\text {LEDSC }}$. When the LED short protection is detected the LED string that is above the threshold will be removed from operation. | On | On | Off for shorted pins. On for all others. |
| Overtemperature Protection | Auto-restart | Always | No | Fault occurs when the die temperature exceeds the overtemperature threshold, $165^{\circ} \mathrm{C}$. | Off | Off | Off |
| VIN UVLO | Auto-restart | Always | No | Fault occurs when $\mathrm{V}_{\text {IN }}$ drops below $\mathrm{V}_{\text {UVLO }}, 3.90 \mathrm{~V}$ maximum. This fault resets all latched faults. | Off | Off | Off |

## APPLICATION INFORMATION

## Design Example for Boost Configuration

This section provides a method for selecting component values when designing an application using the A8502. The resulting design is diagrammed in Figure 35.

Assumptions: For the purposes of this example, the following are given as the application requirements:

- $\mathrm{V}_{\text {BAT }}: 10$ to 14 V
- Quantity of LED channels, $\#_{\text {CHANNELS }}: 2$
- Quantity of series LEDs per channel, \#SERIESLEDS: 10
- LED current per channel, $\mathrm{I}_{\text {LED }}: 120 \mathrm{~mA}$
- LED $_{\mathrm{f}}$ at $120 \mathrm{~mA}: 3.2 \mathrm{~V}$
- $\mathrm{f}_{\mathrm{SW}}: 2 \mathrm{MHz}$
- $\mathrm{T}_{\mathrm{A}}(\max ): 65^{\circ} \mathrm{C}$
- PWM dimming frequency: $200 \mathrm{~Hz}, 1 \%$ duty cycle

Procedure: The procedure consists of selecting the appropriate configuration and then the individual component values, in an ordered sequence.

Step 1: Connect LEDs to pins LED1 and LED2.
Step 2: Determining the LED current setting resistor $\mathrm{R}_{\text {ISET }}$ :

$$
\begin{align*}
R_{\mathrm{ISET}} & =\left(V_{\mathrm{ISET}} \times A_{\mathrm{ISET}}\right) / I_{\mathrm{LED}}  \tag{7}\\
& =(1.003(\mathrm{~V}) \times 980) / 120(\mathrm{~mA})=8.19 \mathrm{k} \Omega
\end{align*}
$$

Choose a $8.25 \mathrm{k} \Omega$ resistor.
Step 3: Determining the OVP resistor. The OVP resistor is connected between the OVP pin and the output voltage of the converter.

Step 3a: The first step is determining the maximum voltage based on the LED requirements. The regulation voltage, $\mathrm{V}_{\text {LED }}$, of the A8502 is 720 mV . A constant term, 2 V , is added to give margin to the design due to noise and output voltage ripple.

$$
\begin{aligned}
V_{\text {OUT }(\mathrm{OVP})} & =\#_{\text {SERIESLEDS }} \times V_{\mathrm{f}}+V_{\mathrm{LED}}+2(\mathrm{~V}) \\
& =10 \times 3.2(\mathrm{~V})+0.720(\mathrm{~V})+2(\mathrm{~V}) \\
& =34.72 \mathrm{~V}
\end{aligned}
$$

Then the OVP resistor is:

$$
\begin{align*}
R_{\mathrm{OVP}} & =\left(V_{\mathrm{OUT}(\mathrm{OVP})}-V_{\mathrm{OVP}(\mathrm{th})}\right) / I_{\mathrm{OVPH}}  \tag{9}\\
& =(34.72 \mathrm{~V}-8.1 \mathrm{~V}) / 199 \mu \mathrm{~A}=133.77 \mathrm{k} \Omega
\end{align*}
$$

where both $\mathrm{I}_{\mathrm{OVPH}}$ and $\mathrm{V}_{\mathrm{OVP}(\text { th })}$ are taken from the Electrical Characteristics table.

Chose a value of resistor that is higher value than the calculated $\mathrm{R}_{\mathrm{OVP}}$. In this case a value of $137 \mathrm{k} \Omega$ was selected. Below is the actual value of the minimum OVP trip level with the selected resistor:

$$
V_{\text {OUT }(\mathrm{OVP})}=137(\mathrm{k} \Omega) \times 199(\mu \mathrm{~A})+8.1(\mathrm{~V})=35.36 \mathrm{~V}
$$

Step 3b: At this point a quick check must be done to determine if the conversion ratio is acceptable for the selected frequency.

$$
\begin{align*}
\mathrm{D}_{\text {maxofboost }} & =1-\mathrm{t}_{\text {SWOFFTIME }} \times \mathrm{f}_{\text {SW }}  \tag{10}\\
& =1-68(\mathrm{~ns}) \times 2(\mathrm{MHz})=86.4 \%
\end{align*}
$$

where the minimum off-time ( $\mathrm{t}_{\text {SWOFFTIME }}$ ) is found in the Electrical Characteristics table.
The Theoretical Maximum $\mathrm{V}_{\text {OUT }}$ is then calculated as:

$$
\begin{align*}
V_{\mathrm{OUT}}(\max ) & =\frac{V_{\mathrm{IN}}(\min )}{1-D_{\text {maxofboost }}}-V_{\mathrm{d}}  \tag{11}\\
& =\frac{10(\mathrm{~V})}{1-0.864}-0.4(\mathrm{~V})=73.13 \mathrm{~V}
\end{align*}
$$

where $V_{d}$ is the diode forward voltage.
The Theoretical Maximum $V_{\text {OUT }}$ value must be greater than the value $\mathrm{V}_{\text {OUT(OVP) }}$. If this is not the case, the switching frequency of the boost converter must be reduced to meet the maximum duty cycle requirements.

Step 4: Selecting the inductor. The inductor must be chosen such that it can handle the necessary input current. In most applications, due to stringent EMI requirements, the system must operate in continuous conduction mode throughout the whole input voltage range.

## Wide Input Voltage Range, High Efficiency Fault Tolerant LED Driver

Step 4a: Determining the duty cycle, calculated as follows:

$$
\begin{align*}
D(\max ) & =1-\frac{V_{\mathrm{IN}}(\min )}{V_{\mathrm{OUT}(\mathrm{OVP})}+V_{\mathrm{d}}}  \tag{12}\\
& =1-\frac{10(\mathrm{~V})}{35.36(\mathrm{~V})+0.4(\mathrm{~V})}=72.04 \%
\end{align*}
$$

Step 4b: Determining the maximum and minimum input current to the system. The minimum input current will dictate the inductor value. The maximum current rating will dictate the current rating of the inductor. First, the maximum input current, given:

$$
\begin{align*}
I_{\mathrm{OUT}} & =\#_{\mathrm{CHANNELS}} \times I_{\mathrm{LED}}  \tag{13}\\
& =2 \times 0.120(\mathrm{~A})=0.240 \mathrm{~A}
\end{align*}
$$

then:

$$
\begin{align*}
I_{\mathrm{IN}}(\max ) & =\frac{V_{\mathrm{OUT}(\mathrm{OVP})} \times I_{\mathrm{OUT}}}{V_{\mathrm{IN}}(\mathrm{~min}) \times \eta}  \tag{14}\\
& =\frac{35.36(\mathrm{~V}) \times 240(\mathrm{~mA})}{10(\mathrm{~V}) \times 0.90}=0.94 \mathrm{~A}
\end{align*}
$$

where $\eta$ is efficiency.
Next, calculate minimum input current, as follows:

$$
\begin{align*}
I_{\mathrm{IN}}(\min ) & =\frac{V_{\mathrm{OUT}(\mathrm{OVP})} \times I_{\mathrm{OUT}}}{V_{\mathrm{IN}}(\max ) \times \eta}  \tag{15}\\
& =\frac{35.36(\mathrm{~V}) \times 240(\mathrm{~mA})}{14(\mathrm{~V}) \times 0.90}=0.67 \mathrm{~A}
\end{align*}
$$

A good approximation of efficiency, $\eta$, can be taken from the efficiency curves located in the datasheet. A value of $90 \%$ is a good starting approximation.
Step 4c: Determining the inductor value. To ensure that the inductor operates in continuous conduction mode, the value of the inductor must be set such that the $1 / 2$ inductor ripple current is not greater than the average minimum input current. As a first pass assume $I_{\text {ripple }}$ to be $40 \%$ of the maximum inductor current:

$$
\begin{align*}
\Delta I_{\mathrm{L}} & =I_{\mathrm{IN}}(\max ) \times I_{\text {ripple }}  \tag{16}\\
& =0.94(\mathrm{~A}) \times 0.40=0.376 \mathrm{~A}
\end{align*}
$$

then:

$$
\begin{aligned}
L & =\frac{V_{\mathrm{IN}}(\min )}{\Delta I_{\mathrm{L}} \times f_{\mathrm{SW}}} \times D(\max ) \\
& =\frac{10(\mathrm{~V})}{0.376(\mathrm{~A}) \times 2(\mathrm{MHz})} \times 0.72=9.57 \mu \mathrm{H}
\end{aligned}
$$

Step 4d: Double-check to make sure the $1 / 2$ current ripple is less than $\mathrm{I}_{\mathrm{IN}}(\mathrm{min})$ :

$$
\begin{gather*}
I_{\mathrm{IN}}(\min )>1 / 2 \Delta I_{\mathrm{L}}  \tag{18}\\
0.67 \mathrm{~A}>0.19 \mathrm{~A}
\end{gather*}
$$

A good inductor value to use would be $10 \mu \mathrm{H}$.
Step 4 e : This step is used to verify that there is sufficient slope compensation for the inductor chosen. The slope compensation value is determined by the following formula:

$$
\begin{equation*}
\text { Slope Compensation }=\frac{3.6 \times f_{\mathrm{SW}}}{2 \times 10^{6}}=3.6 \mathrm{~A} / \mu \mathrm{s} \tag{19}
\end{equation*}
$$

Next insert the inductor value used in the design:

$$
\begin{align*}
\Delta I_{\text {Lused }} & =\frac{V_{\text {IN }}(\min ) \times D(\max )}{L_{\text {used }} \times f_{\text {SW }}}  \tag{20}\\
& =\frac{10(\mathrm{~V}) \times 0.72}{10(\mu \mathrm{H}) \times 2.0(\mathrm{MHz})}=0.36 \mathrm{~A}
\end{align*}
$$

Calculate the minimum required slope:

$$
\begin{align*}
\text { Required Slope }(\min ) & =\frac{\Delta I_{\text {Lused }} \times 1 \times 10^{-6}}{\frac{1}{f_{\mathrm{SW}}} \times(1-D(\max ))}  \tag{21}\\
& =\frac{0.36(\mathrm{~A}) \times 1 \times 10^{-6}}{\frac{1}{2.0(\mathrm{MHz})} \times(1-0.72)}=2.57 \mathrm{~A} / \mu \mathrm{s}
\end{align*}
$$

If the minimum required slope is greater than the calculated slope compensation, the inductor value must be increased.
Note: The slope compensation value is in $\mathrm{A} / \mu \mathrm{s}$, and $1 \times 10^{-6}$ is a constant multiplier.

Step 4f: Determining the inductor current rating. The inductor current rating must be greater than the $I_{\mathrm{IN}}(\max )$ value plus half of the ripple current $\Delta \mathrm{I}_{\mathrm{L}}$, calculated as follows:

$$
\begin{align*}
L(\min ) & =I_{\mathrm{IN}}(\max )+1 / 2 \Delta I_{\text {Lused }}  \tag{22}\\
& =0.94(\mathrm{~A})+0.36(\mathrm{~A}) / 2=1.12 \mathrm{~A}
\end{align*}
$$

Step 5: Determining the resistor value for a particular switching frequency. Use the $\mathrm{R}_{\text {FSET }}$ values shown in Figure 7. For example, a $10 \mathrm{k} \Omega$ resistor will result in a 2 MHz switching frequency.
Step 6: Choosing the proper switching diode. The switching diode must be chosen for three characteristics when it is used in LED lighting circuitry. The most obvious two are: current rating of the diode and reverse voltage rating.

## Wide Input Voltage Range, High Efficiency Fault Tolerant LED Driver

The reverse voltage rating should be such that during operation condition, the voltage rating of the device is larger than the maximum output voltage. In this case it is $\mathrm{V}_{\text {OUT(OVP) }}$.

The peak current through the diode is calculated as:

$$
\begin{align*}
I_{\mathrm{dp}} & =I_{\mathrm{IN}}(\max )+1 / 2 \Delta I_{\text {Lused }}  \tag{23}\\
& =0.94(\mathrm{~A})+0.36(\mathrm{~A}) / 2=1.12 \mathrm{~A}
\end{align*}
$$

The third major component in deciding the switching diode is the reverse current, $I_{R}$, characteristic of the diode. This characteristic is especially important when PWM dimming is implemented.
During PWM off-time the boost converter is not switching. This results in a slow bleeding off of the output voltage, due to leakage currents. $\mathrm{I}_{\mathrm{R}}$ can be a large contributor, especially at high temperatures. On the diode that was selected in this design, the current varies between 1 and $100 \mu \mathrm{~A}$.

Step 7: Choosing the output capacitors. The output capacitors must be chosen such that they can provide filtering for both the boost converter and for the PWM dimming function. The biggest factors that contribute to the size of the output capacitor are: PWM dimming frequency and PWM duty cycle. Another major contributor is leakage current, $\mathrm{I}_{\mathrm{LK}}$. This current is the combination of the OVP leakage current as well as the reverse current of the switching diode. In this design the PWM dimming frequency is 200 Hz and the minimum duty cycle is $1 \%$. Typically, the voltage variation on the output, $\mathrm{V}_{\text {COUT }}$, during PWM dimming must be less than 250 mV , so that no audible hum can be heard. The capacitance can be calculated as follows:

$$
\begin{align*}
C_{\text {OUT }} & =I_{\mathrm{LK}} \times \frac{1-D(\mathrm{~min})}{f_{\text {PWM }(\text { dimming })} \times V_{\text {COUT }}}  \tag{24}\\
& =200(\mu \mathrm{~A}) \times \frac{1-0.01}{200(\mathrm{~Hz}) \times 0.250(\mathrm{~V})}=3.96 \mu \mathrm{~F}
\end{align*}
$$

A capacitor larger than $3.96 \mu \mathrm{~F}$ should be selected due to degradation of capacitance at high voltages on the capacitor. A ceramic $4.7 \mu \mathrm{~F} 50 \mathrm{~V}$ capacitor is a good choice to fulfill this requirement. Corresponding capacitors include:

| Vendor | Value | Part number |
| :--- | :---: | :---: |
| Murata | $4.7 \mu \mathrm{~F} 50 \mathrm{~V}$ | GRM32ER71H475KA88L |
| Murata | $2.2 \mu \mathrm{~F} 50 \mathrm{~V}$ | GRM31CR71H225KA88L |

The rms current through the capacitor is given by:

$$
\begin{align*}
I_{\mathrm{COUT}} \mathrm{rms} & =I_{\mathrm{OUT}} \sqrt{\frac{D(\max )+\frac{\Delta I_{\mathrm{Lused}}}{I_{\mathrm{IN}}(\max ) \times 12}}{1-D(\max )}}  \tag{25}\\
& =0.240(\mathrm{~A}) \sqrt{\frac{0.72+\frac{0.36(\mathrm{~A})}{0.94(\mathrm{~A}) \times 12}}{1-0.72}}=0.39 \mathrm{~A}
\end{align*}
$$

The output capacitor must have a current rating of at least 390 mA . The capacitor selected in this design was a $4.7 \mu \mathrm{~F} 50 \mathrm{~V}$ capacitor with a 3 A current rating.

Step 8: Selecting input capacitor. The input capacitor must be selected such that it provides a good filtering of the input voltage waveform. A good estimation rule is to set the input voltage ripple, $\Delta \mathrm{V}_{\mathrm{IN}}$, to be $1 \%$ of the minimum input voltage. The minimum input capacitor requirements are as follows:

$$
\begin{align*}
C_{\mathrm{IN}} & =\frac{\Delta I_{\text {Lused }}}{8 \times f_{\text {SW }} \times \Delta V_{\text {IN }}}  \tag{26}\\
& =\frac{0.36(\mathrm{~A})}{8 \times 2(\mathrm{MHz}) \times 0.1(\mathrm{~V})}=0.23 \mu \mathrm{~F}
\end{align*}
$$

The rms current through the capacitor is given by:

$$
\begin{align*}
C_{\mathrm{IN}} \mathrm{rms} & =\frac{I_{\mathrm{OUT}} \times \frac{\Delta I_{\text {Lused }}}{I_{\mathrm{IN}}(\max )}}{(1-D) \times \sqrt{12}}  \tag{27}\\
& =\frac{0.240(\mathrm{~A}) \times \frac{0.36(\mathrm{~A})}{0.94(\mathrm{~A})}}{(1-0.72) \times \sqrt{12}}=0.095 \mathrm{~A}
\end{align*}
$$

A good ceramic input capacitor with ratings of $2.2 \mu \mathrm{~F} 50 \mathrm{~V}$ or $4.7 \mu \mathrm{~F} 50 \mathrm{~V}$ will suffice for this application. Corresponding capacitors include:

| Vendor | Value | Part number |
| :---: | :---: | :---: |
| Murata | $4.7 \mu F 50 \mathrm{~V}$ | GRM32ER71H475KA88L |
| Murata | $2.2 \mu \mathrm{~F} 50 \mathrm{~V}$ | GRM31CR71H225KA88L |

## Wide Input Voltage Range, High Efficiency Fault Tolerant LED Driver

Step 9: Choosing the input disconnect switch components. Set the input disconnect 1 X current limit to 3 A by choosing a sense resistor. The calculated maximum value of the sense resistor is:

$$
\begin{align*}
R_{\mathrm{SC}}(\max ) & =V_{\text {SENSEtrip }} / 3.0(\mathrm{~A})  \tag{28}\\
& =0.104(\mathrm{~V}) / 3.0(\mathrm{~A})=0.035 \Omega
\end{align*}
$$

The $\mathrm{R}_{\mathrm{SC}}$ chosen is $0.033 \Omega$, a standard.

The trip point voltage must be:

$$
\begin{align*}
V_{\mathrm{ADJ}} & =3.0(\mathrm{~A}) \times 0.033(\Omega)=0.099(\mathrm{~V}), \text { therefore } \\
R_{\mathrm{ADJ}} & =\left(V_{\mathrm{SENSEtrip}}-V_{\mathrm{ADJ}}\right) / I_{\mathrm{ADJ}}(\text { typ })  \tag{29}\\
& =(0.104(\mathrm{~V})-0.099(\mathrm{~V})) / 20.3(\mu \mathrm{~A})=246.31 \Omega
\end{align*}
$$

A value of $249 \Omega$ was chosen for this design.

Figure 35: The schematic diagram showing calculated values from the design example above.

## Wide Input Voltage Range, High Efficiency Fault Tolerant LED Driver

## Design Example for SEPIC Configuration

This section provides a method for selecting component values when designing an application using the A8502 in SEPIC (Sin-gle-Ended Primary-Inductor Converter) circuit. SEPIC topology has the advantage that it can generate a positive output voltage either higher or lower than the input voltage. The resulting design is diagrammed in Figure 36.
Assumptions: For the purposes of this example, the following are given as the application requirements:

- $\mathrm{V}_{\text {BAT }}: 6$ to 14 V ( $\mathrm{V}_{\mathrm{IN}}(\min ): 5 \mathrm{~V}$ and $\left.\mathrm{V}_{\mathrm{IN}}(\max ): 16 \mathrm{~V}\right)$
- Quantity of LED channels, \# CHANNELS : 2
- Quantity of series LEDs per channel, \# SERIESLEDS : 4
- LED current per channel, $\mathrm{I}_{\text {LED }}: 120 \mathrm{~mA}$
- $\mathrm{LED}_{\mathrm{f}}$ at $120 \mathrm{~mA}: \approx 3.3 \mathrm{~V}$
- $\mathrm{f}_{\mathrm{SW}}: 2 \mathrm{MHz}$
- $\mathrm{T}_{\mathrm{A}}(\max ): 65^{\circ} \mathrm{C}$
- PWM dimming frequency: $200 \mathrm{~Hz}, 1 \%$ duty cycle

Procedure: The procedure consists of selecting the appropriate configuration and then the individual component values, in an ordered sequence.

Step 1: Connect LEDs to pins LED1 and LED2. Note: if only one LED channel is needed, the unused LEDx pin should be pulled to ground using a $1.5 \mathrm{k} \Omega$ resistor. Alternatively, short the LED1 and LED2 pins together, and half the LED current, to 60 mA per channel.

Step 2: Determining the LED current setting resistor $\mathrm{R}_{\text {ISET }}$ :

$$
\begin{align*}
R_{\mathrm{ISET}} & =\left(V_{\mathrm{ISET}} \times A_{\mathrm{ISET}}\right) / I_{\mathrm{LED}}  \tag{30}\\
& =(1.003(\mathrm{~V}) \times 980) / 120 \mathrm{~mA}=8.19 \mathrm{k} \Omega
\end{align*}
$$

Choose a $8.25 \mathrm{k} \Omega$ resistor $1 \%$ resistor (or $16.2 \mathrm{k} \Omega$ if $\mathrm{I}_{\text {LED }}$ is $60 \mathrm{~mA} /$ channel).

Step 3: Determining the OVP resistor. The OVP resistor is connected between the OVP pin and the output voltage of the converter.

Step 3a: The first step is determining the maximum voltage based on the LED requirements. The regulation voltage, $\mathrm{V}_{\text {LED }}$, of the A8502 is 720 mV . A constant term, 2 V , is added to give margin to the design due to noise and output voltage ripple.

$$
\begin{align*}
V_{\mathrm{OUT}(\mathrm{OVP})} & =\#_{\text {SERIESLEDS }} \times V_{\mathrm{f}}+V_{\mathrm{LED}}+2(\mathrm{~V})  \tag{31}\\
& =4 \times 3.2(\mathrm{~V})+0.720(\mathrm{~V})+2(\mathrm{~V})=15.9 \mathrm{~V}
\end{align*}
$$

Then the OVP resistor is:

$$
\begin{align*}
R_{\mathrm{OVP}} & =\left(V_{\mathrm{OUT}(\mathrm{OVP})}-V_{\mathrm{OVP}(\mathrm{th})}\right) / I_{\mathrm{OVPH}}  \tag{32}\\
& =(15.9(\mathrm{~V})-8.1(\mathrm{~V})) / 0.199(\mathrm{~mA})=39.196 \mathrm{k} \Omega
\end{align*}
$$

where both $\mathrm{I}_{\mathrm{OVPH}}$ and $\mathrm{V}_{\mathrm{OVP}(\mathrm{th})}$ are taken from the Electrical Characteristics table.

In this case a value of $39.2 \mathrm{k} \Omega$ was selected. Below is the actual value of the minimum OVP trip level with the selected resistor:

$$
V_{\mathrm{OUT}(\mathrm{OVP})}=39.2(\mathrm{k} \Omega) \times 0.199(\mathrm{~mA})+8.1(\mathrm{~V})=15.9 \mathrm{~V}
$$

Step 3b: At this point a quick check must be done to determine if the conversion ratio is acceptable for the selected frequency.

$$
\begin{align*}
\mathrm{D}_{\max } & =1-\mathrm{t}_{\text {SWOFFTIME }} \times \mathrm{f}_{\text {SW }}  \tag{33}\\
& =1-68(\mathrm{~ns}) \times 2(\mathrm{MHz})=86.4 \%
\end{align*}
$$

where the minimum off-time ( $\mathrm{t}_{\text {SWOFFTIME }}$ ) is found in the Electrical Characteristics table.

The Theoretical Maximum $\mathrm{V}_{\text {OUT }}$ is then calculated as:

$$
\begin{align*}
V_{\mathrm{OUT}}(\max ) & =V_{\mathrm{IN}}(\min ) \times \frac{D_{\max }}{1-D_{\max }}-V_{\mathrm{d}}  \tag{34}\\
& =5(\mathrm{~V}) \times \frac{0.86}{1-0.86}-0.4(\mathrm{~V})=30.3 \mathrm{~V}
\end{align*}
$$

where $V_{d}$ is the diode forward voltage.
The Theoretical Maximum $V_{\text {OUT }}$ value must be greater than the value $\mathrm{V}_{\mathrm{OUT}(\mathrm{OVP})}$. If this is not the case, the switching frequency of the boost converter must be reduced to meet the maximum duty cycle requirements.

## Wide Input Voltage Range, High Efficiency Fault Tolerant LED Driver

Step 4: Selecting the inductor. The inductor must be chosen such that it can handle the necessary input current. In most applications, due to stringent EMI requirements, the system must operate in continuous conduction mode throughout the whole input voltage range.
Step 4a: Determining the duty cycle, calculated as follows:

$$
\begin{align*}
D(\max ) & =\frac{V_{\mathrm{OUT}(\mathrm{OVP})}+V_{\mathrm{d}}}{V_{\mathrm{IN}}(\min )+V_{\mathrm{OUT}(\mathrm{OVP})}+V_{\mathrm{d}}}  \tag{35}\\
& =\frac{15.9(\mathrm{~V})+0.4(\mathrm{~V})}{5(\mathrm{~V})+15.9(\mathrm{~V})+0.4(\mathrm{~V})}=76.5 \%
\end{align*}
$$

Step 4b: Determining the maximum and minimum input current to the system. The minimum input current will dictate the inductor value. The maximum current rating will dictate the current rating of the inductor. First, the maximum input current, given:

$$
\begin{align*}
I_{\mathrm{OUT}} & =\#_{\mathrm{CHANNELS}} \times I_{\mathrm{LED}}  \tag{36}\\
& =2 \times 0.120(\mathrm{~A})=0.240 \mathrm{~A}
\end{align*}
$$

then:

$$
\begin{align*}
I_{\mathrm{IN}}(\max ) & =\frac{V_{\mathrm{OUT}(\mathrm{OVP})} \times I_{\mathrm{OUT}}}{V_{\mathrm{IN}}(\min ) \times \eta}  \tag{37}\\
& =\frac{15.9(\mathrm{~V}) \times 0.24(\mathrm{~A})}{5(\mathrm{~V}) \times 0.90}=0.848 \mathrm{~A}
\end{align*}
$$

where $\eta$ is efficiency.
Next, calculate minimum input current, as follows:

$$
\begin{align*}
I_{\mathrm{IN}}(\min ) & =\frac{V_{\mathrm{OUT}(\mathrm{OVP})} \times I_{\mathrm{OUT}}}{V_{\mathrm{IN}}(\max ) \times \eta}  \tag{38}\\
& =\frac{15.9(\mathrm{~V}) \times 0.24(\mathrm{~A})}{16(\mathrm{~V}) \times 0.90}=0.265 \mathrm{~A}
\end{align*}
$$

A good approximation of efficiency, $\eta$, can be taken from the efficiency curves located in the datasheet. A value of $90 \%$ is a good starting approximation.
Step 4c: Determining the inductor value. To ensure that the inductor operates in continuous conduction mode, the value of
the inductor must be set such that the $1 / 2$ inductor ripple current is not greater than the average minimum input current. As a first pass assume $I_{\text {ripple }}$ to be $30 \%$ of the maximum inductor current:

$$
\begin{align*}
\Delta I_{\mathrm{L}} & =I_{\mathrm{IN}}(\max ) \times I_{\text {ripple }}  \tag{39}\\
& =0.848 \times 0.30=0.254 \mathrm{~A}
\end{align*}
$$

then:

$$
\begin{align*}
L & =\frac{V_{\mathrm{IN}}(\min )}{\Delta I_{\mathrm{L}} \times f_{\mathrm{SW}}} \times D(\max )  \tag{40}\\
& =\frac{5(\mathrm{~V})}{0.254(\mathrm{~A}) \times 2(\mathrm{MHz})} \times 0.765=7.53 \mu \mathrm{H}
\end{align*}
$$

Step 4d: Double-check to make sure the $1 / 2$ current ripple is less than $\mathrm{I}_{\mathrm{IN}}(\mathrm{min})$ :

$$
\begin{align*}
I_{\mathrm{IN}}(\min ) & >1 / 2 \Delta I_{\mathrm{L}}  \tag{41}\\
0.265 \mathrm{~A} & >0.127 \mathrm{~A}
\end{align*}
$$

A good inductor value to use would be $10 \mu \mathrm{H}$.
Step 4e: Next insert the inductor value used in the design to determine the actual inductor ripple current:

$$
\begin{align*}
\Delta I_{\text {Lused }} & =\frac{V_{\text {IN }}(\min ) \times D(\max )}{L_{\text {used }} \times f_{\text {SW }}}  \tag{42}\\
& =\frac{5(\mathrm{~V}) \times 0.765}{10(\mu \mathrm{H}) \times 2.0(\mathrm{MHz})}=0.191 \mathrm{~A}
\end{align*}
$$

Step 4f: Determining the inductor current rating. The inductor current rating must be greater than the $I_{\mathrm{IN}}(\max )$ value plus half of the ripple current $\Delta \mathrm{I}_{\mathrm{L}}$, calculated as follows:

$$
\begin{align*}
L(\min ) & =I_{\mathrm{IN}}(\max )+1 / 2 \Delta I_{\text {Lused }}  \tag{43}\\
& =0.848(\mathrm{~A})+0.096(\mathrm{~A})=0.944 \mathrm{~A}
\end{align*}
$$

Step 5: Determining the resistor value for a particular switching frequency. Use the $\mathrm{R}_{\text {FSET }}$ values shown in Figure 7. For example, a $10 \mathrm{k} \Omega$ resistor will result in a 2 MHz switching frequency.

Step 6: Choosing the proper switching diode. The switching diode must be chosen for three characteristics when it is used in LED lighting circuitry. The most obvious two are: current rating of the diode and reverse voltage rating.

## Wide Input Voltage Range, High Efficiency Fault Tolerant LED Driver

The reverse breakdown voltage rating for the output diode in a SEPIC circuit should be:

$$
\begin{align*}
V_{\mathrm{BD}} & >V_{\mathrm{OUT}(\mathrm{OVP})}(\max )+V_{\mathrm{IN}}(\max )  \tag{44}\\
& >15.9(\mathrm{~V})+16(\mathrm{~V})=31.9 \mathrm{~V}
\end{align*}
$$

because the maximum output voltage in this case is $\mathrm{V}_{\mathrm{OUT}(\mathrm{OVP})}$.
The peak current through the diode is calculated as:

$$
\begin{align*}
I_{\mathrm{dp}} & =I_{\mathrm{IN}}(\max )+1 / 2 \Delta I_{\text {Lused }}  \tag{45}\\
& =0.848(\mathrm{~A})+0.096(\mathrm{~A})=0.944 \mathrm{~A}
\end{align*}
$$

The third major component in deciding the switching diode is the reverse current, $\mathrm{I}_{\mathrm{R}}$, characteristic of the diode. This characteristic is especially important when PWM dimming is implemented. During PWM off-time the boost converter is not switching. This results in a slow bleeding off of the output voltage, due to leakage currents. $\mathrm{I}_{\mathrm{R}}$ can be a large contributor, especially at high temperatures. On the diode that was selected in this design, the current varies between 1 and $100 \mu \mathrm{~A}$. It is often advantageous to pick a diode with a much higher breakdown voltage, just to reduce the reverse current. Therefore for this example, pick a diode rated for a $V_{B D}$ of 60 V , instead of just 40 V .

Step 7: Choosing the output capacitors. The output capacitors must be chosen such that they can provide filtering for both the boost converter and for the PWM dimming function. The biggest factors that contribute to the size of the output capacitor are: PWM dimming frequency and PWM duty cycle. Another major contributor is leakage current, $\mathrm{I}_{\mathrm{LK}}$. This current is the combination of the OVP leakage current as well as the reverse current of the switching diode. In this design the PWM dimming frequency is 200 Hz and the minimum duty cycle is $1 \%$. Typically, the voltage variation on the output, $\mathrm{V}_{\text {COUT }}$, during PWM dimming must be less than 250 mV , so that no audible hum can be heard. The capacitance can be calculated as follows:

$$
\begin{aligned}
C_{\mathrm{OUT}} & =I_{\mathrm{LK}} \times \frac{1-D(\mathrm{~min})}{f_{\mathrm{PWM}(\text { dimming })} \times V_{\mathrm{COUT}}} \\
& =200(\mu \mathrm{~A}) \times \frac{1-0.01}{200(\mathrm{~Hz}) \times 0.250(\mathrm{~V})}=3.96 \mu \mathrm{~F}
\end{aligned}
$$

A capacitor larger than $3.96 \mu \mathrm{~F}$ should be selected due to degradation of capacitance at high voltages on the capacitor. Select a $4.7 \mu \mathrm{~F}$ capacitor for this application.

The rms current through the capacitor is given by:

$$
\begin{align*}
I_{\mathrm{COUT}} \mathrm{rms} & =I_{\mathrm{OUT}} \sqrt{\frac{D(\max )}{1-D(\max )}}  \tag{47}\\
& =0.240(\mathrm{~A}) \sqrt{\frac{0.765}{1-0.765}}=0.433 \mathrm{~A}
\end{align*}
$$

The output capacitor must have a ripple current rating of at least 500 mA . The capacitor selected for this design is a $4.7 \mu \mathrm{~F} 50 \mathrm{~V}$ capacitor with a 1.5 A current rating.

Step 8: Selecting input capacitor. The input capacitor must be selected such that it provides a good filtering of the input voltage waveform. A estimation rule is to set the input voltage ripple, $\Delta \mathrm{V}_{\mathrm{IN}}$, to be $1 \%$ of the minimum input voltage. The minimum input capacitor requirements are as follows:

$$
\begin{align*}
C_{\mathrm{IN}} & =\frac{\Delta I_{\text {Lused }}}{8 \times f_{\mathrm{SW}} \times \Delta V_{\mathrm{IN}}}  \tag{48}\\
& =\frac{0.191(\mathrm{~A})}{8 \times 2(\mathrm{MHz}) \times 0.05(\mathrm{~V})}=0.24 \mu \mathrm{~F}
\end{align*}
$$

The rms current through the capacitor is given by:

$$
\begin{align*}
C_{\mathrm{IN}} \mathrm{rms} & =\frac{\Delta I_{\mathrm{Lused}}}{\sqrt{12}}  \tag{49}\\
& =\frac{0.191(\mathrm{~A})}{\sqrt{12}}=0.055 \mathrm{~A}
\end{align*}
$$

A good ceramic input capacitor with a rating of $2.2 \mu \mathrm{~F} 25 \mathrm{~V}$ will suffice for this application.

## Wide Input Voltage Range, High Efficiency Fault Tolerant LED Driver

Step 9: Selecting coupling capacitor $\mathrm{C}_{\mathrm{SW}}$. The minimum capacitance of $\mathrm{C}_{\mathrm{SW}}$ is related to the maximum voltage ripple allowed across it:

$$
\begin{align*}
C_{\mathrm{SW}} & =\frac{I_{\mathrm{OUT}} \times D_{\mathrm{MAX}}}{\Delta V_{\mathrm{SW}} \times f_{\mathrm{SW}}}  \tag{50}\\
& =\frac{0.24(\mathrm{~A}) \times 0.765}{0.1(\mathrm{~V}) \times 2(\mathrm{MHz})}=0.92 \mu \mathrm{~F}
\end{align*}
$$

The rms current requirement of the coupling capacitor is given by:

$$
\begin{align*}
I_{\mathrm{CSW}} \mathrm{rms} & =I_{\mathrm{IN}} \sqrt{\frac{1-D(\max )}{D(\max )}}  \tag{51}\\
& =0.848(\mathrm{~A}) \sqrt{\frac{1-0.765}{0.765}}=0.47 \mathrm{~A}
\end{align*}
$$

The voltage rating of the coupling capacitor must be greater than $\mathrm{V}_{\text {IN }}(\max )$, or 16 V in this case. A ceramic capacitor rated for $2.2 \mu \mathrm{~F} 25 \mathrm{~V}$ will suffice for this application.

Figure 36: Typical application showing SEPIC configuration, designed according to the application example.

## Package LP, 16-Pin TSSOP with Exposed Thermal Pad

Revision History

| Number | Date |  |
| :---: | :---: | :--- |
| 3 | January 16, 2012 | Update Features list and $\mathrm{g}_{\mathrm{m}}$ |
| 4 | July 8, 2014 | Updated FSET resistance and typical switching frequency |
| 5 | December 1, 2014 | Updated specifications on EC table |
| 6 | October 1, 2015 | Added Figure 11, and renumbered subsequent figures |
| 7 | February 27, 2017 | Corrected SYNC Input Logic Voltage values on page 6 |
| 8 | March 13, 2019 | Updated Sync section (page 15) |
