### Contents

Se	Section number		Title	Page
		A	Chapter 1 bout This Document	
1.1	Overvie	ew		27
	1.1.1	Purpose		27
	1.1.2	Audience		
1.2	Conven	tions		
	1.2.1	Numbering systems		27
	1.2.2	Typographic notation		
	1.2.3	Special terms		
			Chapter 2 Introduction	
2.1	Introdu	ction		
2.2	Module	functional categories		
	2.2.1	S08L core modules		
	222	Containing 1 1 an		20

	2.2.2	System modules	. 30
	2.2.3	Memories and memory interfaces	31
	2.2.4 Clocks		31
	2.2.5	Security and integrity modules	. 31
	2.2.6	Analog modules	. 32
	2.2.7	Timer modules	. 32
	2.2.8 Communication interfaces		. 33
	2.2.9	Human-machine interfaces	. 33
2.3	MCU blo	ock diagram	. 33
2.4	Orderabl	e part numbers	34

### Chapter 3 Pins and connections

3.1	Device pin assignment
3.2	Pin functions

#### 3.2.1 3.2.2 3.2.3 3.2.4 3.2.5 3.2.6 3.2.7 Port B input/output (I/O) pins (PTB7–PTB0)......42 3.2.8 3.3

Title

### Chapter 4 Power management

4.1	Introduction		
4.2	Features		
	4.2.1	Run mode	45
	4.2.2	Wait mode	46
	4.2.3	Stop3 mode	46
	4.2.4	Active BDM enabled in stop3 mode	46
	4.2.5	LVD enabled in stop mode	47
	4.2.6	Power modes behaviors	47
4.3	Low vol	tage detect (LVD) system	48
	4.3.1	Power-on reset (POR) operation	49
	4.3.2	LVD reset operation	49
	4.3.3	Low-voltage warning (LVW)	49
4.4	Power n	nanagement control bits and registers	50
	4.4.1	System Power Management Status and Control 1 Register (PMC_SPMSC1)	50
	4.4.2	System Power Management Status and Control 2 Register (PMC_SPMSC2)	52

#### Chapter 5 Memory map

5.1	Memory map	53
	* 1

5.2	Periphe	eral register	addresses	
5.3	Rando	m-access me	emory (RAM)	
5.4	Flash n	nemory		57
			Chapter 6 Interrupt	
6.1	Interru	pts		
	6.1.1	Interrupt	stack frame	
	6.1.2	Interrupt	vectors, sources, and local masks	61
	6.1.3	Hardware	e nested interrupt	63
		6.1.3.1	Interrupt priority level register	65
		6.1.3.2	Interrupt priority level comparator set	
		6.1.3.3	Interrupt priority mask update and restore mechanism	65
		6.1.3.4	Integration and application of the IPC	
6.2	IRQ			67
	6.2.1	Features.		67
		6.2.1.1	Pin configuration options	68
		6.2.1.2	Edge and level sensitivity	
6.3	Interru	pt pin reque	est register	69
	6.3.1	Interrupt	Pin Request Status and Control Register (IRQ_SC)	69
6.4	Interru	pt priority c	control register	
	6.4.1	IPC Statu	is and Control Register (IPC_SC)	71
	6.4.2	Interrupt	Priority Mask Pseudo Stack Register (IPC_IPMPS)	
	6.4.3	Interrupt	Level Setting Registers n (IPC_ILRSn)	73
			Chapter 7 System control	

7.1	System device identification (SDID)	.75
7.2	Universally unique identification (UUID)	.75
7.3	Reset and system initialization	75
7.4	System options	.76

Sec	ction n	umber Title	Page	
	7.4.1	BKGD pin enable		
	7.4.2	RESET pin enable		
	7.4.3	SCI0 pin reassignment		
	7.4.4	I2C pins reassignments		
	7.4.5	FTM0 channels pin reassignment		
7.5	System interconnection		77	
	7.5.1	ACMP output selection	77	
	7.5.2	SCI0 TxD modulation		
	7.5.3	SCI0 RxD capture		
	7.5.4	SCI0 RxD filter		
	7.5.5	RTC capture		
	7.5.6	ADC hardware trigger	79	
7.6	FTM sc	ftware controlled output		
7.7	System Control Registers			
	7.7.1	System Reset Status Register (SYS_SRS)		
	7.7.2	System Background Debug Force Reset Register (SYS_SBDFR)	84	
	7.7.3	System Device Identification Register: High (SYS_SDIDH)		
	7.7.4	System Device Identification Register: Low (SYS_SDIDL)		
	7.7.5	System Options Register 1 (SYS_SOPT1)		
	7.7.6	System Options Register 2 (SYS_SOPT2)		
	7.7.7	System Options Register 3 (SYS_SOPT3)		
	7.7.8	System Options Register 4 (SYS_SOPT4)		
	7.7.9	System Options Register 5 (SYS_SOPT5)		
	7.7.10	System Options Register 6 (SYS_SOPT6)		
	7.7.11	System Options Register 7 (SYS_SOPT7)		
	7.7.12	System Options Register 8 (SYS_SOPT8)		
	7.7.13	System Clock Gating Control 1 Register (SYS_SCGC1)		
	7.7.14	System Clock Gating Control 2 Register (SYS_SCGC2)		
	7.7.15	System Clock Gating Control 3 Register (SYS_SCGC3)

			Flash Memory Module (FTMRH)	
10.1	Introduc	tion		
10.2	Feature.			
	10.2.1	Flash men	nory features	
	10.2.2	Other flash	h module features	
10.3	Function	nal descripti	ion	
	10.3.1 Modes of operation			
		10.3.1.1	Wait mode	
		10.3.1.2	Stop mode	
	10.3.2	Flash bloc	k read access	
	10.3.3	Flash men	nory map	141
	10.3.4	Flash initia	alization after system reset	141
	10.3.5	Flash com	mand operations	141
		10.3.5.1	Writing the FCLKDIV register	
		10.3.5.2	Command write sequence	
	10.3.6	Flash inter	rrupts	146
		10.3.6.1	Description of flash interrupt operation	
	10.3.7	Protection	l	
	10.3.8	Security		
		10.3.8.1	Unsecuring the MCU using backdoor key access	
		10.3.8.2	Unsecuring the MCU using BDM	
		10.3.8.3	Mode and security effects on flash command availability	
	10.3.9	Flash com	mands	
		10.3.9.1	Flash commands	
	10.3.10	Flash com	mand summary	
		10.3.10.1	Erase Verify All Blocks command	
		10.3.10.2	Erase Verify Block command	
		10.3.10.3	Erase Verify Flash Section command	
		10.3.10.4	Read once command

## Chapter 1 About This Document

## 1.1 Overview

## 1.1.1 Purpose

This document describes the features, architecture, and programming model of the NXP microcontrollers.

## 1.1.2 Audience

A reference manual is primarily for system architects and software application developers who are using or considering using an NXP product in a system.

## 1.2 Conventions

## 1.2.1 Numbering systems

The following suffixes identify different numbering systems:

This suffix	Identifies a
b	Binary number. For example, the binary equivalent of the number 5 is written 101b. In some cases, binary numbers are shown with the prefix <i>Ob</i> .
d	Decimal number. Decimal numbers are followed by this suffix only when the possibility of confusion exists. In general, decimal numbers are shown without a suffix.
h	Hexadecimal number. For example, the hexadecimal equivalent of the number 60 is written 3Ch. In some cases, hexadecimal numbers are shown with the prefix <i>0x</i> .

## 1.2.2 Typographic notation

The following typographic notation is used throughout this document:

Example	Description
placeholder, x	Items in italics are placeholders for information that you provide. Italicized text is also used for the titles of publications and for emphasis. Plain lowercase letters are also used as placeholders for single letters and numbers.
code	Fixed-width type indicates text that must be typed exactly as shown. It is used for instruction mnemonics, directives, symbols, subcommands, parameters, and operators. Fixed-width type is also used for example code. Instruction mnemonics and directives in text and tables are shown in all caps; for example, BSR.
SR[SCM]	A mnemonic in brackets represents a named field in a register. This example refers to the Scaling Mode (SCM) field in the Status Register (SR).
REVNO[6:4], XAD[7:0]	<ul><li>Numbers in brackets and separated by a colon represent either:</li><li>A subset of a register's named field</li></ul>
	For example, REVNO[6:4] refers to bits 6–4 that are part of the COREREV field that occupies bits 6–0 of the REVNO register.
	<ul> <li>A continuous range of individual signals of a bus</li> </ul>
	For example, XAD[7:0] refers to signals 7–0 of the XAD bus.

## 1.2.3 Special terms

The following terms have special meanings:

Term	Meaning
asserted	<ul> <li>Refers to the state of a signal as follows:</li> <li>An active-high signal is asserted when high (1).</li> <li>An active-low signal is asserted when low (0).</li> </ul>
deasserted	<ul> <li>Refers to the state of a signal as follows:</li> <li>An active-high signal is deasserted when low (0).</li> <li>An active-low signal is deasserted when high (1).</li> </ul>
	In some cases, deasserted signals are described as <i>negated</i> .
reserved	Refers to a memory space, register, or field that is either reserved for future use or for which, when written to, the module or chip behavior is unpredictable.

## Chapter 2 Introduction

## 2.1 Introduction

The MC9S08PL16S devices are highly-integrated, low-power and low pin count 8-bit microcontrollers based on the S08L core platform.

The features are as follows:

- Maximum CPU frequency of 20 MHz which is used as bus frequency
- Scalable memory options, up to 16 KB Flash and 1 KB RAM
- Operating voltage ranges from 2.7 V to 5.5 V with full functional Flash program/ erase/read operations
- Multiple package options of 20-pin and 16-pin
- Ambient operating temperature ranges from -40 °C to 85 °C

## 2.2 Module functional categories

The modules on this device are grouped into functional categories. Information found here describes the modules assigned to each category in more detail.

Module category	Description
HCS08 core	8-bit MCU core, 20 MHz CPU frequency.
System	<ul> <li>System integration module</li> <li>Power management and mode controllers <ul> <li>Multiple power modes available based on run, wait, stop, and power-down modes</li> </ul> </li> <li>Interrupt priority controller (IPC)</li> </ul>
Memories	<ul> <li>Up to 16 KB flash memory for PL16S and up to 8 KB flash memory for PL8S</li> <li>Up to 1 KB SRAM</li> </ul>
Clocks	Internal clock source     31.25 to 39.0625 kHz IRC

 Table 2-1.
 Module functional categories

Table continues on the next page...

Module category	Description
	<ul> <li>20 kHz oscillator with functional in all power modes</li> <li>Frequency-locked loop</li> <li>Oscillator (OSC), loop-controlled pierce oscillator; crystal or ceramic resonator range of 31.25 kHz to 39.0625 kHz or 4MHz to 20 MHz</li> <li>DC to 20 MHz</li> </ul>
Security	<ul><li>Windowed COP watchdog</li><li>One cyclic redundancy check (CRC)</li></ul>
Analog	<ul> <li>One 10-bit analog-to-digital converters (ADC)</li> <li>One high speed comparator (CMP) with internal 6-bit digital-to-analog converter (DAC)</li> </ul>
Timers	<ul> <li>Up to two 16-bit FTM modules</li> <li>One 8-bit modulo timer (MTIM) module</li> <li>One real timer clock (RTC)</li> </ul>
Communications	<ul> <li>One inter-integrated circuit (l<sup>2</sup>C) module</li> <li>One serial communications interface (SCI)</li> </ul>
Human-Machine Interfaces (HMI)	<ul><li>Port control (PORT)</li><li>One keyboard interrupt (KBI)</li></ul>

Table 2-1.	Module functional	categories	(continued)
		Jacogonioo	(0011011000)

## 2.2.1 S08L core modules

The following core modules are available on this device.

### Table 2-2. Core modules

Module	Description
HCS08 V6 CPU	The HCS08 CPU is fully source- and object-code-compatible with the M68HC08 CPU. Several instructions and enhanced addressing modes were added to improve C compiler efficiency and to support a new background debug system which replaces the monitor mode of earlier M68HC08 microcontrollers.
Debug module	The DBG module implements an on-chip ICE (in-circuit emulation) system and allows non-intrusive debug of application software by providing an on-chip trace buffer with flexible triggering capability. The trigger can also provide extended breakpoint capacity. The on-chip ICE system is optimized for the HCS08 8-bit architecture and supports 64 KB of memory space.

## 2.2.2 System modules

The following system modules are available on this device.

Module	Description
System Control module (SYS)	The SYS includes integration logic and several module configuration settings.
Power management controller (PMC)	The PMC provides the user with multiple power options. Multiple modes are supported that allow the user to optimize power consumption for the level of functionality needed. Includes power-on-reset (POR) and integrated low voltage detect (LVD) with reset (brownout) capability and selectable LVD trip points.
Development support	Development supports single-wire background debug mode (BDM), which uses the on-chip background debug controller (BDC) module, and the independent on-chip realtime in-circuit emulation (ICE) system, which uses the on-chip debug (DBG) module.
Debug module (DBG)	The DBG module implements an on-chip ICE (in-circuit emulation) system and allows non-intrusive debug of application software by providing an on-chip trace buffer with flexible triggering capability.

Table 2-3.System modules

## 2.2.3 Memories and memory interfaces

The following memories and memory interfaces are available on this device.

Module	Description
-	Program flash memory — up to 16 KB or 8 KB of the non-volatile flash memory that can execute program code.

Table 2-4. Memories and memory interfaces

Up to 1 KB random-access memory (RAM).

## 2.2.4 Clocks

SRAM

The following clock modules are available on this device.

Table 2-5. Clock modules

Module	Description
Internal Clock Source (ICS)	ICS module containing an internal reference clock (ICSIRCLK) and a frequency locked loop (FLL).
Oscillator (OSC)	The OSC module, in conjunction with an external crystal or resonator, generates a clock for the MCU that can be used as reference clock or bus clock.
Low-Power Oscillator (LPO)	The PMC module contains a 1 kHz low-power oscillator which acts as a standalone low-frequency clock source in all modes.

## 2.2.5 Security and integrity modules

The following security and integrity modules are available on this device:

Module	Description	
Windowed COP watchdog (WCOP)	The COP watchdog is used to force a system reset when the application software fails to execute as expected.	
Cyclic Redundancy Check (CRC)	The cyclic redundancy check (CRC) module generates 16/32-bit CRC code for error detection.	

## 2.2.6 Analog modules

The following analog modules are available on this device:

Module	Description		
Analog-to-digital converters (ADC)	10-bit successive-approximation ADC module.		
Comparator (CMP)	One comparator that compares two analog input voltages across the full range of the supply voltage and can trigger an ADC acquisition, FTM update, or CPU interrupt.		
6-bit digital-to-analog converters (DAC)	64-tap resistor ladder network which provides a selectable voltage reference for comparator.		

## 2.2.7 Timer modules

The following timer modules are available on this device:

Table 2-8. Timer modules

Module	Description
FlexTimer Module (FTM)	<ul> <li>Selectable FTM source clock, programmable prescaler</li> <li>16-bit counter supporting free-running, and counting is up or up-down</li> <li>Input capture, output compare, and edge-aligned and center-aligned PWM modes</li> <li>Operation of FTM channels as pairs with equal outputs or independent channels with independent outputs</li> <li>Programmable interrupt on input capture, reference compare, overflowed counter</li> </ul>
8-bit modulo timer (MTIM)	<ul> <li>8-bit up-counter</li> <li>Four software selectable clock sources for input to prescaler</li> <li>Nine selectable clock prescale values</li> <li>Modulo compare matched can be an output</li> </ul>

Table continues on the next page...

Table 2-8.	Timer modules	(continued)
------------	---------------	-------------

Module	Description		
	The RTC is consisting of one 16-bit counter, one 16-bit comparator, several binary- based and decimal-based prescaler dividers, two clock sources, and one programmable periodic interrupt.		

## 2.2.8 Communication interfaces

The following communication interfaces are available on this device:

Table 2-9.	Communication modules
------------	-----------------------

Module	Description	
Inter-integrated circuit (I2C)	Allows communication between a number of devices. Also supports the System Management Bus (SMBus) Specification, version 2.	
Serial communications interface (SCI)	SCI is used to connect to the RS232 serial input/output port of a personal computer or workstation and communicate with other embedded controllers.	

## 2.2.9 Human-machine interfaces

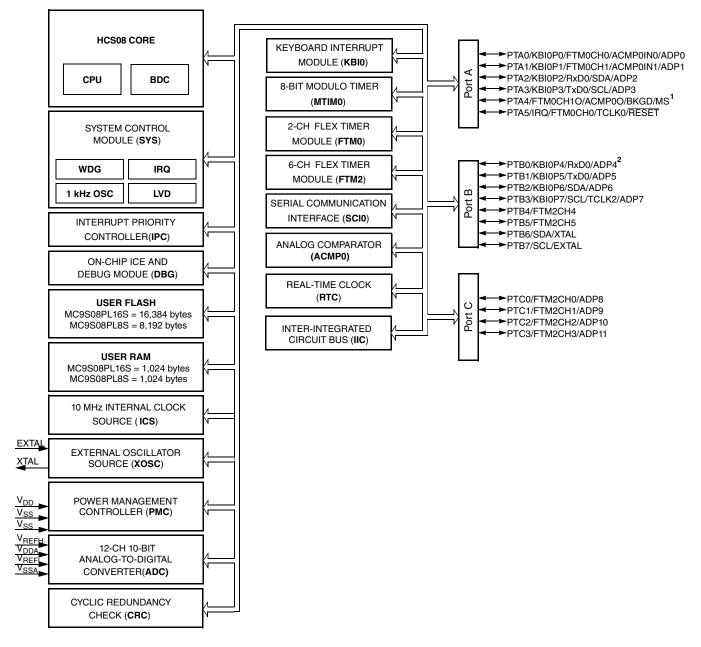

The following human-machine interfaces (HMI) are available on this device:

Module	Description		
Port Control (PORT)	Some general purpose input or output pins are capable of interrupt request generation.		
Keyboard Interrupts (KBI)	<ul> <li>Up to eight keyboard interrupt pins with individual pin enable bits</li> <li>Each keyboard interrupt pin is programmable</li> <li>One software-enabled keyboard interrupt</li> <li>Exit from low-power modes</li> </ul>		

## 2.3 MCU block diagram

The block diagram below shows the structure of the MCUs.

#### Orderable part numbers

1. PTA4/FTM0CH1O/ACMP0O/BKGD/MS is an output-only pin when used as port pin.

2. PTB0 operates as true-open drain when working as output.

## 2.4 Orderable part numbers

The following table summarizes the part numbers of the devices covered by this document.

Feature	MC9S08PL16S				MC9S08PL8S		
Part number	СТЈ	CTG	CSC <sup>1</sup>	СТЈ	СТС	CSC <sup>1</sup>	
Max. frequency (MHz)	20	20	20	20	20	20	
Flash memory (KB)	16	16	16	8	8	8	
RAM (KB)	1	1	1	1	1	1	
10-bit ADC	12ch	8ch	4ch	12ch	8ch	4ch	
ACMP	1	1	1	1	1	1	
16-bit FlexTimer	6ch+2ch	2ch+2ch	2ch	6ch+2ch	2ch+2ch	2ch	
8-bit Modulo timer	1	1	1	1	1	1	
RTC	Yes	Yes	Yes	Yes	Yes	Yes	
12C	1	1	1	1	1	1	
SCI (LIN Capable)	1	1	1	1	1	1	
WCOP	Yes	Yes	Yes	Yes	Yes	Yes	
CRC	Yes	Yes	Yes	Yes	Yes	Yes	
KBI pins	8	8	4	8	8	4	
GPIO	18	14	6	18	14	6	
Package	20-TSSOP	16-TSSOP	8-SOIC	20-TSSOP	16-TSSOP	8-SOIC	

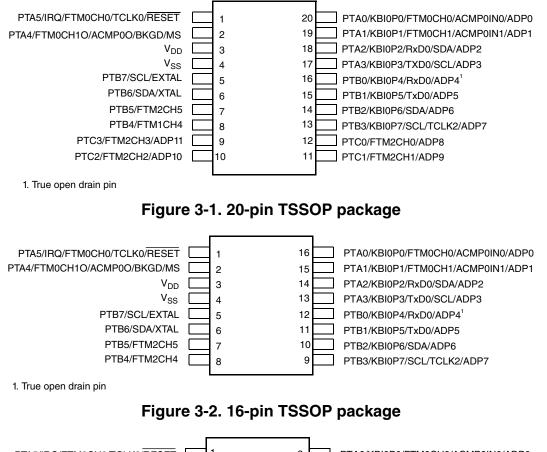

## Table 2-11. Orderable part numbers summary

1. To confirm current availability of ordererable part numbers, go to http://www.nxp.com and perform a part number search.

# Chapter 3 Pins and connections

# 3.1 Device pin assignment

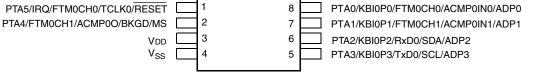

Figure 3-3. 8-pin SOIC package

# 3.2 Pin functions

### 3.2.1 Power ( $V_{DD}$ , $V_{SS}$ )

 $V_{DD}$  and  $V_{SS}$  are the primary power supply pins for the MCU. This voltage source supplies power to all I/O buffer circuitry and to an internal voltage regulator. The internal voltage regulator provides a regulated lower-voltage source to the CPU and to the MCU's other internal circuitry.

Typically, application systems have two separate capacitors across the power pins. In this case, there should be a bulk electrolytic capacitor, such as a 10  $\mu$ F tantalum capacitor, that provides bulk charge storage for the overall system and a 0.1  $\mu$ F ceramic bypass capacitor located as near to the paired V<sub>DD</sub> and V<sub>SS</sub> power pins as practical to suppress high-frequency noise.

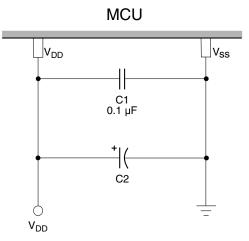

Figure 3-4. Power supply bypassing

# 3.2.2 Analog power supply and reference pins (V<sub>DDA</sub>/V<sub>REFH</sub> and V<sub>SSA</sub>/V<sub>REFL</sub>)

 $V_{DDA}$  and  $V_{SSA}$  are the power supply pins for the analog-to-digital converter (ADC). Connect the  $V_{DDA}$  pin to the same voltage potential as  $V_{DD}$ , and the  $V_{SSA}$  pin to the same voltage potential as  $V_{SS}$ .

De-coupling of these pins should be as per the digital supply. A 0.1  $\mu$ F ceramic bypass capacitor should be located as near to the MCU power pins as practical to suppress high-frequency noise.

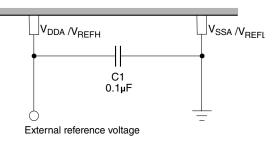

Figure 3-5. Analog power supply bypassing

 $V_{REFH}$  is the high reference supply for the ADC, and is internally connected to  $V_{DDA}$ .  $V_{REFL}$  is the low reference supply for the ADC, and is internally connected to  $V_{SSA}$ .

#### 3.2.3 Oscillator (XTAL, EXTAL)

The XTAL and EXTAL pins are used to provide the connections for the on-chip oscillator. The oscillator (XOSC) in this MCU is a Pierce oscillator that can accommodate a crystal or ceramic resonator. Optionally, an external clock source can be connected to the EXTAL input pin. The oscillator can be configured to run in stop3 mode.

Refer to the following figure,  $R_S$  (when used) and  $R_F$  must be low-inductance resistors such as carbon composition resistors. Wire-wound resistors, and some metal film resistors, have too much inductance. C1 and C2 normally must be high-quality ceramic capacitors that are specifically designed for high-frequency applications.

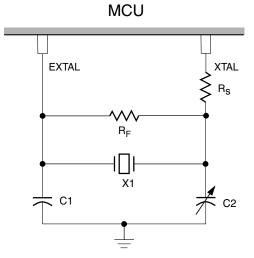

Figure 3-6. Typical crystal or resonator circuit

#### Pin functions

 $R_F$  is used to provide a bias path to keep the EXTAL input in its linear range during crystal startup; its value is not generally critical. Typical systems use 1 M to 10 M. Higher values are sensitive to humidity and lower values reduce gain and (in extreme cases) could prevent startup.

C1 and C2 are typically in the 5 pF to 25 pF range and are chosen to match the requirements of a specific crystal or resonator. Take into account printed circuit board (PCB) capacitance and MCU pin capacitance when selecting C1 and C2. The crystal manufacturer typically specifies a load capacitance, which is the series combination of C1 and C2 (which are usually the same size). As a first-order approximation, use 10 pF as an estimate of combined pin and PCB capacitance for each oscillator pin (EXTAL and XTAL).

### 3.2.4 External reset pin (RESET) and interrupt pin (IRQ)

A low on the  $\overline{\text{RESET}}$  pin forces the MCU to a known startup state.  $\overline{\text{RESET}}$  is bidirectional, allowing a reset of the entire system. It is driven low when any internal reset source is asserted. This pin contains an internal pullup resistor.

RESET shares an I/O pin with PTA5. The RESET pin function is enabled by default after POR reset, because internal power-on reset and low-voltage reset circuitry typically make external reset circuitry unnecessary. This pin is normally connected to the standard 6-pin background debug connector so that a development system can directly reset the MCU system. If RESET function of PTA5/IRQ/FTM0CH0/TCLK0/RESET pin is enabled, a manual external reset can be added by supplying a simple switch to ground (pull reset pin low to force a reset). When the RESET pin function is enabled, an internal pullup resistor is connected to this pin and a reset signal can feed into MCU with an input hysteresis. POR reset brings RESET pin into its default configuration, reset other than POR has no effect on the RESET pin function configuration.

When PTA5/IRQ/FTM0CH0/TCLK0/RESET is enabled as IRQ pin, it is the input source for the IRQ interrupt and is also the input for the BIH and BIL instructions. IRQ is asynchronous external interrupt pins.

In EMC-sensitive applications, an external RC filter is recommended on the reset pin. See the following figure for example.

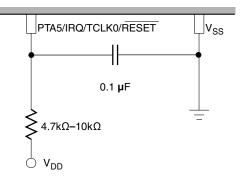

Figure 3-7. PTA5/IRQ/FTM0CH0/TCLK0/RESET external RC filter

#### 3.2.5 Background/mode select (BKGD/MS)

During a power-on-reset (POR) or background debug force reset, the PTA4/FTM0CH1O/ ACMP0O/BKGD/MS pin functions as a mode select pin. Immediately after internal reset rises the pin functions as the background pin and can be used for background debug communication. While the pin functions as a background/mode selection pin, it includes an internal pullup device and a standard output driver.

The background debug communication function is enabled when SOPT1[BKGDPE] bit is set. SOPT1[BKGDPE] is set following any reset of the MCU and must be cleared to use the PTA4/FTM0CH1O/ACMP0O/BKGD/MS pin's alternative pin functions.

If this pin is floating, the MCU will enter normal operating mode at the rising edge of reset. If a debug system is connected to the 6-pin standard background debug header, it can hold BKGD/MS low during the POR or immediately after issuing a background debug force reset, which will force the MCU into active background mode.

The BKGD pin is used primarily for background debug controller (BDC) communications using a custom protocol that uses 16 clock cycles of the target MCU's BDC clock per bit time. The target MCU's BDC clock can run as fast as the bus clock, so there should never be any significant capacitance connected to the BKGD/MS pin that interferes with background serial communications. When the pin performs output only PTA4, it can drive only capacitance-limited MOSFET. Driving a bipolar transistor directly by PTA4 is prohibited because this can cause mode entry fault and BKGD errors.

Although the BKGD pin is a pseudo open-drain pin, the background debug communication protocol provides brief, actively driven, high speedup pulses to ensure fast rise time. Small capacitances from cables and the absolute value of the internal pullup device play almost no role in determining rise and fall time on the BKGD pin.

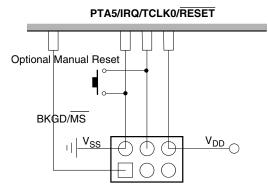

Figure 3-8. Typical debug circuit

### 3.2.6 Port A input/output (I/O) pins (PTA5-PTA0)

PTA5–PTA0 are general-purpose, bidirectional I/O port pins. These port pins also have selectable pullup devices when configured for input mode except PTA4. The pullup devices are selectable on an individual port bit basis. The pulling devices are disengaged when configured for output mode.

PTA4 is output only when used as port pin. The pulling device is disabled at this condition.

### 3.2.7 Port B input/output (I/O) pins (PTB7–PTB0)

PTB7–PTB0 are general-purpose, bidirectional I/O port pins. These port pins also have selectable pullup devices when configured for input mode, the pullup devices are selectable on an individual port bit basis. The pulling devices are disengaged when configured for output mode.

## 3.2.8 Port C input/output (I/O) pins (PTC7–PTC0)

PTC3–PTC0 are general-purpose, bidirectional I/O port pins. These port pins also have selectable pullup devices when configured for input mode, and the pullup devices are selectable on an individual port bit basis. The pulling devices are disengaged when configured for output mode.

# 3.3 Peripheral pinouts

These MCUs support up to 18 general-purpose I/O pins, which are shared with on-chip peripheral functions (FTM, ACMP, ADC, SCI, KBI, etc.). These 18 general-purpose I/O pins include one output-only pin (PTA4).

When a port pin is configured as general-purpose input, or when a peripheral uses the port pin as an input, the software can enable a pullup device.

For information about controlling these pins as general-purpose I/O pins, see the Port Control. For information about how and when on-chip peripheral systems use these pins, see the appropriate module chapter.

Immediately after reset, all pins are configured as high-impedance general-purpose IO with internal pullup devices disabled.

	Pin number			Lowest Priority <> Highest					
20-TSSOP	16-TSSOP	8-SOIC	Port Pin	Alt 1	Alt 2	Alt 3	Alt 4	Alt 5	
1	1	1	PTA5	IRQ	FTM0CH0	TCLK0	-	RESET

Table 3-1. Pin availability by package pin-count

1. This is a true open-drain pin when operated as output.

#### NOTE

When an alternative function is first enabled, it is possible to get a spurious edge to the module. User software must clear any associated flags before interrupts are enabled. The table above illustrates the priority if multiple modules are enabled. The highest priority module will have control over the pin. Selecting a higher priority pin function with a lower priority function already enabled can cause spurious edges to the lower priority module. Disable all modules that share a pin before enabling another module.

# Chapter 4 Power management

### 4.1 Introduction

The operating modes of the device are described in this chapter. Entry into each mode, exit from each mode, and functionality while in each of the modes are described.

### 4.2 Features

These MCUs feature the following power modes:

- Run mode
- Wait mode
  - CPU shuts down to conserve power
  - Bus clocks are running
  - Full voltage regulation is maintained
- Stop3 modes
  - System clocks stopped; voltage regulator in standby
  - all internal circuits powered for fast recovery

### 4.2.1 Run mode

This is the normal operating mode. In this mode, the CPU executes code from internal memory with execution beginning at the address fetched from memory at 0xFFFE: 0xFFFF after reset. The power supply is fully regulating and all peripherals can be active in run mode.

### 4.2.2 Wait mode

Wait mode is entered by executing a WAIT instruction. Upon execution of the WAIT instruction, the CPU enters a low-power state in which it is not clocked. The I bit in CCR is cleared when the CPU enters the wait mode, enabling interrupts. When an interrupt request occurs, the CPU exits the wait mode and resumes processing, beginning with the stacking operations leading to the interrupt service routine.

While the MCU is in wait mode, there are some restrictions on which background debug commands can be used. Only the BACKGROUND command and memory-access-with-status commands are available when the MCU is in wait mode. The memory-access-with-status commands do not allow memory access, but they report an error indicating that the MCU is in either stop or wait mode. The BACKGROUND command can be used to wake the MCU from wait mode and enter active background mode.

### 4.2.3 Stop3 mode

To enter stop3, the user must execute a STOP instruction with stop mode enabled (SOPT1[STOPE] = 1). Upon entering the stop3 mode, all of the clocks in the MCU are halted by default, but OSC clock and internal reference clock can be turned on by setting the ICS control registers. The ICS enters its standby state, as does the voltage regulator and the ADC. The states of all of the internal registers and logic, as well as the RAM content, are maintained. The I/O pin states are not latched at the pin. Instead they are maintained by virtue of the states of the internal logic driving the pins being maintained.

Exit from stop3 is done by asserting reset or through an interrupt. The interrupt include the asynchronous interrupt from the IRQ or KBI pins, the SCI receive interrupt, the ADC, ACMP, I<sup>2</sup>C or LVI interrupt and the real-time interrupt.

If stop3 is exited by means of the  $\overline{\text{RESET}}$  pin, then the MCU will be reset and operation will resume after taking the reset vector. Exit by means of an asynchronous interrupt or the real-time interrupt will result in the MCU taking the appropriate interrupt vector.

The LPO ( $\approx$ 1 kHz) for the real-time counter clock allows a wakeup from stop3 mode with no external components. When RTC\_SC2[RTCPS] is clear, the real-time counter clock function is disabled.

### 4.2.4 Active BDM enabled in stop3 mode

Entry into the active background mode from run mode is enabled if the BDC\_SCR[ENBDM] bit is set. This register is described in the development support. If BDC\_SCR[ENBDM] is set when the CPU executes a STOP instruction, the system clocks to the background debug logic remain active when the MCU enters stop mode, so background debug communication is still possible. In addition, the voltage regulator does not enter its low-power standby state but maintains full internal regulation.

Most background commands are not available in stop mode. The memory-access-withstatus commands do not allow memory access, but they report an error indicating that the MCU is in either stop or wait mode. The BACKGROUND command can be used to wake the MCU from stop and enter active background mode if the BDC\_SCR[ENBDM] bit is set. After entering background debug mode, all background commands are available.

# 4.2.5 LVD enabled in stop mode

The LVD system is capable of generating either an interrupt or a reset when the supply voltage drops below the LVD voltage. If the LVD is enabled in stop (LVDE and LVDSE bits in SPMSC1 both set) at the time the CPU executes a STOP instruction, then the voltage regulator remains active during stop3 mode.

## 4.2.6 Power modes behaviors

Executing the WAIT or STOP command puts the MCU in a low power consumption mode for standby situations. The system integration module (SIM) holds the CPU in a non-clocked state. The operation of each of these modes is described in the following subsections. Both STOP and WAIT clear the interrupt mask (I) in the condition code register, allowing interrupt to occur. The following table shows the low power mode behaviors.

Mode	Run	Wait	Stop3
PMC	Full regulation	Full regulation	Loose regulation
ICS	On	On	Optional on
OSC	On	On	Optional on
LPO	On	On	On
CPU	On	Standby	Standby
FLASH	On	On	Standby

 Table 4-1.
 Low power mode behavior

FTM	On	On	Standby
WDOG	On	On	Optional on
KBI	On	On	Optional on
DBG	On	On	Standby
IPC	On	On	Standby
CRC	On	On	Standby
RTC	On	On	Optional on
LVD	On	On	Optional on

 Table 4-1. Low power mode behavior (continued)

# 4.3 Low voltage detect (LVD) system

This device includes a system to protect against low voltage conditions in order to protect memory contents and control MCU system states during supply voltage variations. This system consists of a power-on reset (POR) circuit and an LVD circuit with a user selectable trip voltage, either high ( $V_{LVDH}$ ) or low ( $V_{LVDL}$ ). The LVD circuit is enabled when SPMSC1[LVDE] is set and the trip voltage is selected by SPMSC2[LVDV]. The LVD is disabled upon entering the stop modes unless the SPMSC1[LVDSE] bit is set or active BDM enabled (BDCSCR[ENBDM]=1). If SPMSC1[LVDSE] and SPMSC1[LVDE] are both set, the current consumption in stop3 with the LVD enabled will be greater.

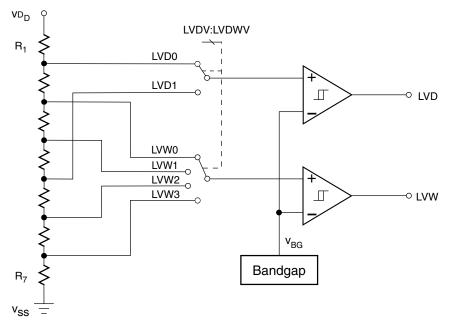

Figure 4-1. Low voltage detect (LVD) block diagram

### 4.3.1 Power-on reset (POR) operation

When power is initially applied to the MCU, or when the supply voltage drops below the  $V_{POR}$  level, the POR circuit will cause a reset condition. As the supply voltage rises, the LVD circuit will hold the chip in reset until the supply has risen above the  $V_{LVDL}$  level. Both the SRS[POR] and SRS[LVD] are set following a POR.

### 4.3.2 LVD reset operation

The LVD can be configured to generate a reset upon detection of a low voltage condition by setting SPMSC1[LVDRE] to 1. After an LVD reset has occurred, the LVD system will hold the MCU in reset until the supply voltage has risen above the level determined by LVDV. The SRS[LVD] bit is set following either an LVD reset or POR.

## 4.3.3 Low-voltage warning (LVW)

The LVD system has a low voltage warning flag to indicate that the supply voltage is approaching the LVD voltage. When a low voltage condition is detected and the LVD circuit is configured for interrupt operation (SPMSC1[LVDE] set, SPMSC1[LVWIE] set), SPMSC1[LVWF] will be set and LVW interrupt will occur. There are four user-selectable trip voltages for the LVW upon each LVDV configuration. The trip voltage is selected by SPMSC2[LVWV].

#### MC9S08PL16S Reference Manual, Rev. 3, 06/2020

# 4.4 Power management control bits and registers

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
3040	System Power Management Status and Control 1 Register (PMC_SPMSC1)	8	R/W	1Ch	4.4.1/50
3041	System Power Management Status and Control 2 Register (PMC_SPMSC2)	8	R/W	00h	4.4.2/52

#### **PMC** memory map

# 4.4.1 System Power Management Status and Control 1 Register (PMC\_SPMSC1)

This high page register contains status and control bits to support the low-voltage detection function, and to enable the bandgap voltage reference for use by the ADC module. This register should be written during the user's reset initialization program to set the desired controls, even if the desired settings are the same as the reset settings.

Address: 3040h base + 0h offset = 3040h

Bit	7	6	5	4	3	2	1	0
Read	LVWF	0	LVWIE	LVDRE	LVDSE	LVDE	BGBDS	BGBE
Write		LVWACK			LVDSL	LVDL	DODDS	DODE
Reset	0	0	0	1	1	1	0	0

#### **PMC\_SPMSC1** field descriptions

Field	Description
7 LVWF	Low-Voltage Warning Flag
	The LVWF bit indicates the low-voltage warning status.
	<b>NOTE:</b> LVWF will be set in the case when V <sub>Supply</sub> transitions below the trip point or after reset and V <sub>Supply</sub> is already below V <sub>LVW</sub> . LVWF bit may be 1 after power on reset, therefore, to use LVW interrupt function, before enabling LVWIE, LVWF must be cleared by writing LVWACK first.
	0 Low-voltage warning is not present.
	1 Low-voltage warning is present or was present.
6 LVWACK	Low-Voltage Warning Acknowledge
	If LVWF = 1, a low-voltage condition has occurred. To acknowledge this low-voltage warning, write 1 to LVWACK, which automatically clears LVWF to 0 if the low-voltage warning is no longer present.
5 LVWIE	Low-Voltage Warning Interrupt Enable

Table continues on the next page...

#### PMC\_SPMSC1 field descriptions (continued)

Field	Description
	This bit enables hardware interrupt requests for LVWF.
	0 Hardware interrupt disabled (use polling).
	1 Request a hardware interrupt when LVWF = 1.
4	Low-Voltage Detect Reset Enable
LVDRE	This write-once bit enables LVD events to generate a hardware reset (provided LVDE = 1).
	<b>NOTE:</b> This bit can be written only one time after reset. Additional writes are ignored.
	0 LVD events do not generate hardware resets.
	1 Force an MCU reset when an enabled low-voltage detect event occurs.
3 LVDSE	Low-Voltage Detect Stop Enable
LVD3L	Provided LVDE = 1, this read/write bit determines whether the low-voltage detect function operates when the MCU is in stop mode.
	0 Low-voltage detect disabled during stop mode.
	1 Low-voltage detect enabled during stop mode.
2 LVDE	Low-Voltage Detect Enable
	This write-once bit enables low-voltage detect logic and qualifies the operation of other bits in this register.
	<b>NOTE:</b> This bit can be written only one time after reset. Additional writes are ignored.
	0 LVD logic disabled.
	1 LVD logic enabled.
1 BGBDS	Bandgap Buffer Drive Select
BGBDS	This bit is used to select the high drive mode of the bandgap buffer.
	0 Bandgap buffer enabled in low drive mode if BGBE = 1.
	1 Bandgap buffer enabled in high drive mode if BGBE = 1.
0 BGBE	Bandgap Buffer Enable
	This bit enables an internal buffer for the bandgap voltage reference for use by the ADC module on one of its internal channels.
	0 Bandgap buffer disabled.
	1 Bandgap buffer enabled.

# 4.4.2 System Power Management Status and Control 2 Register (PMC\_SPMSC2)

This register is used to report the status of the low-voltage warning function, and to configure the stop mode behavior of the MCU. This register should be written during the user's reset initialization program to set the desired controls, even if the desired settings are the same as the reset settings.

Address: 3040h base + 1h offset = 3041h

Bit	7	6	5	4	3	2	1	0
Read	0	LVDV	LVWV		0			
Write								
Reset	0	0	0	0	0	0	0	0

Field	Description
7	This field is reserved.
Reserved	This read-only field is reserved and always has the value 0.
6 LVDV	Low-Voltage Detect Voltage Select
	This write-once bit selects the low-voltage detect (LVD) trip point setting. See data sheet for details.
	0 Low trip point selected ( $V_{LVD} = V_{LVDL}$ ).
	1 High trip point selected ( $V_{LVD} = V_{LVDH}$ ).
5–4 LVWV	Low-Voltage Warning Voltage Select
	This bit selects the low-voltage warning (LVW) trip point voltage. See data sheet for details.
	00 Low trip point selected ( $V_{LVW} = V_{LVW1}$ ).
	01 Middle 1 trip point selected ( $V_{LVW} = V_{LVW2}$ ).
	10 Middle 2 trip point selected ( $V_{LVW} = V_{LVW3}$ ).
	11 High trip point selected ( $V_{LVW} = V_{LVW4}$ ).
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

#### PMC\_SPMSC2 field descriptions

# Chapter 5 Memory map

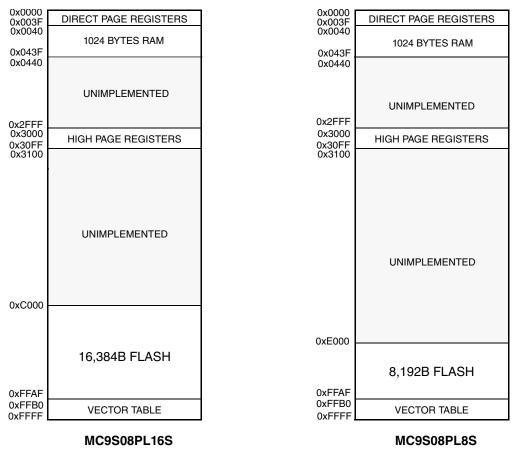

# 5.1 Memory map

In this device, the most frequently used registers are placed in the direct page, memory 0x0000 to 0x003F. Also a portion of RAM is placed in the direct page to take advantage of the direct addressing mode of the CPU. All other register locations in the extended page are the same in terms of instruction cycle times. The placement of the other peripheral modules is not critical because CPU instructions for all other extended memory have the same timing requirements.

As shown below, on-chip memory in this device consists of RAM and flash program memory for nonvolatile data storage, plus I/O and control/status registers. The registers are divided into three groups: direct-page registers, high-page registers and nonvolatile registers.

- User flash memory (flash)
  - MC9S08PL16S: 16,384 bytes; 32 pages of 512 bytes each
  - MC9S08PL8S: 8,192 bytes; 16 pages of 512 bytes each
- Random-access memory (RAM)
  - MC9S08PL16S: 1,024 bytes
  - MC9S08PL8S: 1,024 bytes
- Direct-page registers (0x0000 through 0x003F)
- High-page registers (0x3000 through 0x30FF)

#### 5.2 Peripheral register addresses

The following table shows the register availability of the devices.

Table 5-1. Peripheral regis	ster addresses
-----------------------------	----------------

Address	Size (Byte)	Peripheral
0x0000-0x0002	3	Port data
0x0010-0x0017	8	ADC
0x0018-0x001B	4	МТІМО

0x30F8-0x30FF	8	SYS (UUID)

Table 5-1. Peripheral register addresses (continued)

Several reserved flash memory locations, shown in the following table, are used for storing values used by several registers. These registers include an 8-byte backdoor key, NV\_BACKKEY, which can be used to gain access to secure memory resources. During reset events, the contents of NVPROT and NVOPT in the reserved flash memory are transferred into corresponding FPROT and FOPT registers in the high-page registers area to control security and block protection options

Table 5-2. Reserved flash memory addresses

Address	Register Name	Bit 7	6	5	4	3	2	1	Bit 0
0xFF6E	NV_FTRIM	—	—	—	—	—	—	—	FTRIM

0xFF7E	NV_FOPT	NV							
0xFF7F	NV_FSEC	KEY	/EN	1	1	1	1	SE	EC

 Table 5-2.
 Reserved flash memory addresses (continued)

The 8-byte comparison key can be used to temporarily disengage memory security provided the key enable field, NV\_FSEC[KEYEN], is 10b. This key mechanism can be accessed only through user code running in secure memory. A security key cannot be entered directly through background debug commands. This security key can be disabled completely by programming the NV\_FSEC[KEYEN] bit to 0b. If the security key is disabled, the only way to disengage security is by mass erasing the flash if needed, normally through the background debug interface and verifying that flash is blank. To avoid returning to secure mode after the next reset, program the security bits, NV\_FSEC[SEC], to the unsecured state (10b).

## 5.3 Random-access memory (RAM)

This section describes the 1024 bytes of RAM (random-access memory).

These devices include static RAM. The locations in RAM below 0x0100 can be accessed using the more efficient direct addressing mode. Any single bit in this area can be accessed with the bit manipulation instructions (BCLR, BSET, BRCLR, and BRSET).

The RAM retains data when the MCU is in low-power wait, or stop3 mode. At power-on, the contents of RAM are uninitialized. RAM data is unaffected by any reset provided that the supply voltage does not drop below the minimum value for RAM retention.

For compatibility with older M68HC05 MCUs, the HCS08 resets the stack pointer to 0x00FF. In this series, re-initialize the stack pointer to the top of the RAM so that the direct-page RAM can be used for frequently accessed RAM variables and bit-addressable program variables. Include the following 2-instruction sequence in your reset initialization routine (where RamLast is equated to the highest address of the RAM in the equate file).

LDHX #RamLast+1 ;point one past RAM TXS ;SP<-(H:X-1) When security is enabled, the RAM is considered a secure memory resource and is not accessible through BDM or code executing from non-secure memory.

## 5.4 Flash memory

This device includes flash memory. The flash memory is ideal for single-supply applications that allow for field reprogramming without requiring external high voltage sources for program or erase operations. The flash module includes a memory controller that executes commands to modify flash memory contents. The user interface to the memory controller consists of the indexed flash common command object (FCCOB) register, which is written to with the command, global address, data, and any required command parameters. The memory controller must complete the execution of a command before the FCCOB register is written to with a new command.

#### CAUTION

A flash byte or longword must be in the erased state before being programmed. Cumulative programming of bits within a flash byte or longword is not allowed.

The flash memory is read as two bytes per read. Read access time is one bus cycle for two bytes. For flash memory, an erased bit reads 1 and a programmed bit reads 0.

# Chapter 6 Interrupt

## 6.1 Interrupts

Interrupts save the current CPU status and registers, execute an interrupt service routine (ISR), and then restore the CPU status so that processing resumes where it left off before the interrupt. Other than the software interrupt (SWI), which is a program instruction, interrupts are caused by hardware events such as an edge on the IRQ pin or a timer-overflow event. The debug module can also generate an SWI under certain circumstances.

If an event occurs in an enabled interrupt source, an associated read-only status flag will be set. The CPU will not respond unless only the local interrupt enable is a logic 1. The I bit in the CCR is 0 to allow interrupts. The global interrupt mask (I bit) in the CCR is initially set after reset that masks (prevents) all maskable interrupt sources. The user program initializes the stack pointer and performs other system setups before clearing the I bit to allow the CPU to respond to interrupts.

When the CPU receives a qualified interrupt request, it completes the current instruction before responding to the interrupt. The interrupt sequence obeys the same cycle-by-cycle sequence as the SWI instruction and consists of:

- Saving the CPU registers on the stack.
- Setting the I bit in the CCR to mask further interrupts.
- Fetching the interrupt vector for the highest-priority interrupt that is currently pending.
- Filling the instruction queue with the first three bytes of program information starting from the address fetched from the interrupt vector locations.

While the CPU is responding to the interrupt, the I bit is automatically set to prevent another interrupt from interrupting the ISR itself, which is called nesting of interrupts. Normally, the I bit is restored to 0 when the CCR is restored from the value stacked on

MC9S08PL16S Reference Manual, Rev. 3, 06/2020

#### Interrupts

entry to the ISR. In rare cases, the I bit may be cleared inside an ISR, after clearing the status flag that generated the interrupt, so that other interrupts can be serviced without waiting for the first service routine to finish. This practice is recommended only for the most experienced programmers because it can lead to subtle program errors that are difficult to debug.

The interrupt service routine ends with a return-from-interrupt (RTI) instruction that restores the CCR, A, X, and PC registers to their pre-interrupt values by reading the previously saved information off the stack.

#### Note

For compatibility with the M68HC08, the H register is not automatically saved and restored. Push H onto the stack at the start of the interrupt service routine (ISR) and restore it immediately before the RTI that is used to return from the ISR.

When two or more interrupts are pending when the I bit is cleared, the highest priority source is serviced first.

#### 6.1.1 Interrupt stack frame

The following figure shows the contents and organization of a stack frame. Before the interrupt, the stack pointer (SP) points at the next available byte location on the stack. The current values of CPU registers are stored on the stack, starting with the low-order byte of the program counter (PC) and ending with the CCR. After stacking, the SP points at the next available location on the stack, which is the address that is one less than the address where the CCR was saved. The PC value that is stacked is the address of the instruction in the main program that would have executed next if the interrupt had not occurred.

**Chapter 6 Interrupt** 

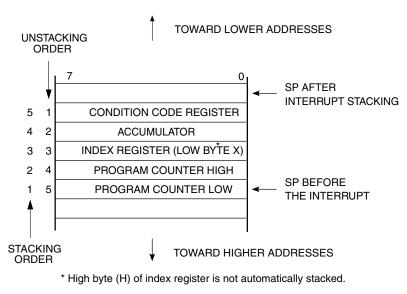

Figure 6-1. Interrupt stack frame

When an RTI instruction executes, these values are recovered from the stack in reverse order. As part of the RTI sequence, the CPU fills the instruction pipeline by reading three bytes of program information, starting from the PC address recovered from the stack.

The status flag causing the interrupt must be acknowledged (cleared) before returning from the ISR. Typically, the flag must be cleared at the beginning of the ISR because if another interrupt is generated by this source it will be registered so that it can be serviced after completion of the current ISR.

### 6.1.2 Interrupt vectors, sources, and local masks

The following table provides a summary of all interrupt sources. High-priority sources are located toward the bottom of the table. The high-order byte of the address for the interrupt service routine is located at the first address in the vector address column, and the low-order byte of the address for the interrupt service routine is located at the next higher address.

When an interrupt condition occurs, an associated flag bit is set. If the associated local interrupt enable is 1, an interrupt request is sent to the CPU. If the global interrupt mask (I bit in the CCR) is 0, the CPU finishes the current instruction, stacks the PCL, PCH, X, A, and CCR CPU registers, sets the I bit, and then fetches the interrupt vector for the highest priority pending interrupt. Processing then continues in the interrupt service routine.

Table 6-1. Reset and interrupt vectors (continued)

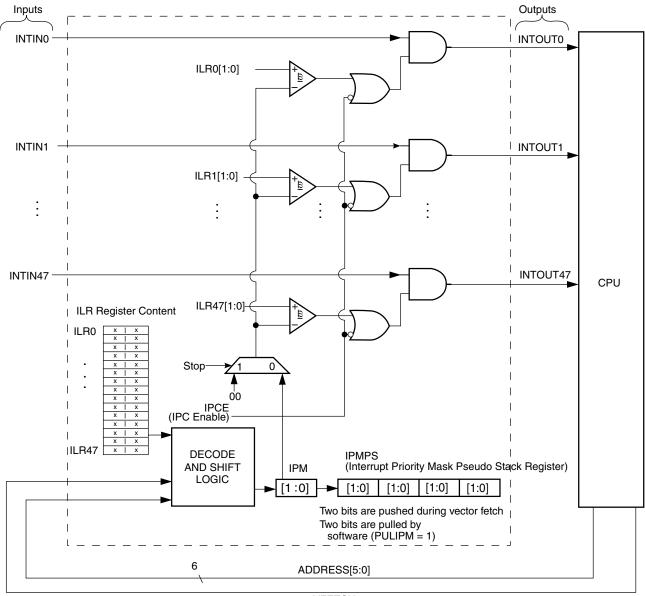

#### 6.1.3 Hardware nested interrupt

This device has interrupt priority controller (IPC) module to provide up to four-level nested interrupt capability. IPC includes the following features:

- Four-level programmable interrupt priority for each interrupt source.
- Support for prioritized preemptive interrupt service routines
  - Low-priority interrupt requests are blocked when high-priority interrupt service routines are being serviced.
  - Higher or equal priority level interrupt requests can preempt lower priority interrupts being serviced.
- Automatic update of interrupt priority mask with being serviced interrupt source priority level when the interrupt vector is being fetched.

Interrupts

- Interrupt priority mask can be modified during main flow or interrupt service execution.
- Previous interrupt mask level is automatically stored when interrupt vector is fetched (four levels of previous values accommodated)

VFETCH

Figure 6-2. Interrupt priority controller block diagram

The IPC works with the existing HCS08 interrupt mechanism to allow nested interrupts with programmable priority levels. This module also allows implementation of preemptive interrupt according to the programmed interrupt priority with minimal software overhead. The IPC consists of three major functional blocks:

- The interrupt priority level registers
- The interrupt priority level comparator set
- The interrupt mask register update and restore mechanism

#### 6.1.3.1 Interrupt priority level register

This set of registers is associated with the interrupt sources to the HCS08 CPU. Each interrupt priority level is a 2-bit value such that a user can program the interrupt priority level of each source to priority 0, 1, 2, or 3. Level 3 has the highest priority while level 0 has the lowest. Software can read or write to these registers at any time. The interrupt priority level comparator set, interrupt mask register update, and restore mechanism use this information.

#### 6.1.3.2 Interrupt priority level comparator set

When the module is enabled, an active interrupt request forces a comparison between the corresponding ILR and the 2-bit interrupt mask IPM[1:0]. In stop3 mode, the IPM[1:0] is substituted by value 00b. If the ILR value is greater than or equal to the value of the interrupt priority mask (IPM bits in IPCSC), the corresponding interrupt out (INTOUT) signal will be asserted and signals an interrupt request to the HCS08 CPU.

When the module is disabled, the interrupt request signal from the source is directly passed to the CPU.

The interrupt priority level programmed in the interrupt priority register will not affect the inherent interrupt priority arbitration as defined by the HCS08 CPU because the IPC is an external module. Therefore, if two (or more) interrupts are present in the HCS08 CPU at the same time, the inherent priority in HCS08 CPU will perform arbitration by the inherent interrupt priority.

#### 6.1.3.3 Interrupt priority mask update and restore mechanism

The interrupt priority mask (IPM) is two bits located in the least significant end of IPCSC register. These two bits control which interrupt is allowed to be presented to the HCS08 CPU. During vector fetch, the interrupt priority mask is updated automatically with the value of the ILR corresponding to that interrupt source. The original value of the IPM will be saved onto IPMPS for restoration after the interrupt service routine completes execution. When the interrupt service routine completes execution, the user restore the

```
Interrupts
```

original value of IPM by writing 1 to the IPCSC[PULIPM] bit. In both cases, the IPMPS is a shift register functioning as a pseudo stack register for storing the IPM. When the IPM is updated, the original value is shifted into IPMPS. The IPMPS can store four levels of IPM. If the last position of IPMPS is written, the PSF flag indicates that the IPMPS is full. If all the values in the IPMPS were read, the PSE flag indicates that the IPMPS is empty.

### 6.1.3.4 Integration and application of the IPC

All interrupt inputs that comes from peripheral modules are synchronous signals. None of the asynchronous signals of the interrupts are routed to IPC. The asynchronous signals of the interrupts are routed directly to SIM module to wake system clocks in stop3 mode.

Additional care must be exercised when IRQ is reprioritized by IPC. CPU instructions BIL and BIH need input from IRQ pin. If IRQ interrupt is masked, BIL and BIH still work but the IRQ interrupt will not occur.

• The interrupt priority controller must be enabled to function. While inside an interrupt service routine, some work has to be done to enable other higher priority interrupts. The following is a pseudo code example written in assembly language:

```
INT_SER :
    BCLR INTFLAG,INTFLAG_R ; clear flag that generate interrupt
    ; do the most critical part
    ; do the most critical part
    ; which it cannot be interrupted
    .
    CLI
enabled
.
BSET PULIPM, PULIPM_R ; restore the old IPM value before leaving
    ; then you can return
```

- A minimum overhead of six bus clock cycles is added inside an interrupt services routine to enable preemptive interrupts.
- As an interrupt of the same priority level is allowed to pass through IPC to HCS08 CPU, the flag generating the interrupt must be cleared before doing CLI to enable preemptive interrupts.

- The IPM is automatically updated to the level the interrupt is servicing and the original level is kept in IPMPS. Watch out for the full (PSF) bit if nesting for more than four levels is expected.
- Before leaving the interrupt service routine, the previous levels must be restored manually by setting PULIPM bit. Watch out for the full (PSF) bit and empty (PSE) bit.

# 6.2 IRQ

The IRQ (external interrupt) module provides a maskable interrupt input.

### 6.2.1 Features

Features of the IRQ module include:

- A Dedicated External Interrupt Pin IRQ
- IRQ Interrupt Control Bits
- Programmable Edge-only or Edge and Level Interrupt Sensitivity
- Automatic Interrupt Acknowledge
- Internal pullup device

A low level applied to the external interrupt request (IRQ) pin can latch a CPU interrupt request. The following figure shows the structure of the IRQ module:

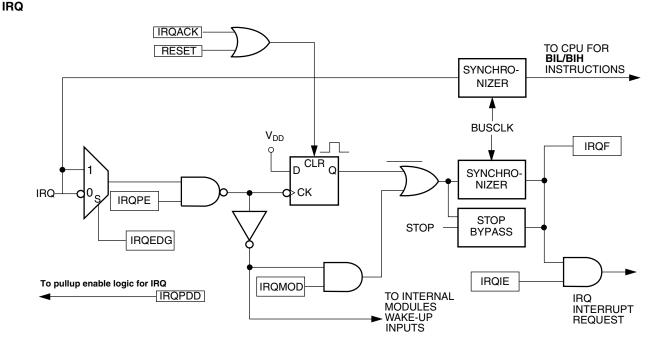

Figure 6-3. IRQ module block diagram

External interrupts are managed by the IRQSC status and control register. When the IRQ function is enabled, synchronous logic monitors the pin for edge-only or edge-and-level events. When the MCU is in stop mode and system clocks are shut down, a separate asynchronous path is used so that the IRQ, if enabled, can wake the MCU.

#### 6.2.1.1 Pin configuration options

The IRQ pin enable control bit (IRQSC[IRQPE]) must be 1 for the IRQ pin to act as the IRQ input. The user can choose the polarity of edges or levels detected (IRQEDG), whether the pin detects edges-only or edges and levels (IRQMOD), or whether an event causes an interrupt or only sets the IRQF flag, which can be polled by software.

When enabled, the IRQ pin defaults to use an internal pullup device (IRQSC[IRQPDD] = 0). If the user uses an external pullup or pulldown, the IRQSC[IRQPDD] can be written to a 1 to turn off the internal device.

BIH and BIL instructions may be used to detect the level on the IRQ pin when it is configured to act as the IRQ input.

#### Note

This pin does not contain a clamp diode to  $V_{DD}$  and must not be driven above  $V_{DD}$ . The voltage measured on the internally pullup IRQ pin may be as low as  $V_{DD} - 0.7$  V. The internal gates connected to this pin are pulled all the way to  $V_{DD}$ .

When enabling the IRQ pin for use, the IRQF will be set, and must be cleared prior to enabling the interrupt. When configuring the pin for falling edge and level sensitivity in a 3 V system, it is necessary to wait at least cycles between clearing the flag and enabling the interrupt.

#### 6.2.1.2 Edge and level sensitivity

The IRQSC[IRQMOD] control bit reconfigures the detection logic so that it can detect edge events and pin levels. In this detection mode, the IRQF status flag is set when an edge is detected, if the IRQ pin changes from the de-asserted to the asserted level, but the flag is continuously set and cannot be cleared as long as the IRQ pin remains at the asserted level.

### 6.3 Interrupt pin request register

Absolute address (hex)	Register name		Access	Reset value	Section/ page
3B	Interrupt Pin Request Status and Control Register (IRQ_SC)	8	R/W	00h	6.3.1/69

#### **IRQ** memory map

#### 6.3.1 Interrupt Pin Request Status and Control Register (IRQ\_SC)

This direct page register includes status and control bits, which are used to configure the IRQ function, report status, and acknowledge IRQ events.

Address: 3Bh base + 0h offset = 3Bh

Bit	7	6	5	4	3	2	1	0
Read	0	IRQPDD	IRQEDG	IRQPE	IRQF	0	IRQIE	IRQMOD
Write			INQEDG	Indi L		IRQACK	INGL	IIIQIIIOD
Reset	0	0	0	0	0	0	0	0

#### IRQ\_SC field descriptions

Field	Description
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 IRQPDD	Interrupt Request (IRQ) Pull Device Disable

Table continues on the next page ...

#### MC9S08PL16S Reference Manual, Rev. 3, 06/2020

#### IRQ\_SC field descriptions (continued)

Field	Description
	This read/write control bit is used to disable the internal pullup device when the IRQ pin is enabled (IRQPE = 1) allowing for an external device to be used.
	0 IRQ pull device enabled if IRQPE = 1.
	1 IRQ pull device disabled if IRQPE = 1.
5 IRQEDG	Interrupt Request (IRQ) Edge Select
	This read/write control bit is used to select the polarity of edges or levels on the IRQ pin that cause IRQF to be set. The IRQMOD control bit determines whether the IRQ pin is sensitive to both edges and levels or only edges. When the IRQ pin is enabled as the IRQ input and is configured to detect rising edges, the optional pullup resistor is disabled.
	0 IRQ is falling edge or falling edge/low-level sensitive.
	1 IRQ is rising edge or rising edge/high-level sensitive.
4 IRQPE	IRQ Pin Enable
	This read/write control bit enables the IRQ pin function. When this bit is set the IRQ pin can be used as an interrupt request.
	0 IRQ pin function is disabled.
	1 IRQ pin function is enabled.
3 IRQF	IRQ Flag
	This read-only status bit indicates when an interrupt request event has occurred.
	0 No IRQ request.
	1 IRQ event detected.
2 IRQACK	IRQ Acknowledge
	This write-only bit is used to acknowledge interrupt request events (write 1 to clear IRQF). Writing 0 has no meaning or effect. Reads always return 0. If edge-and-level detection is selected (IRQMOD = 1), IRQF cannot be cleared while the IRQ pin remains at its asserted level.
1 IRQIE	IRQ Interrupt Enable
	This read/write control bit determines whether IRQ events generate an interrupt request.
	0 Interrupt request when IRQF set is disabled (use polling).
	1 Interrupt requested whenever IRQF = 1.
0 IRQMOD	IRQ Detection Mode
	This read/write control bit selects either edge-only detection or edge-and-level detection.
	0 IRQ event on falling/rising edges only.
	1 IRQ event on falling/rising edges and low/high levels.

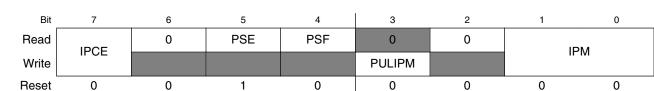

# 6.4 Interrupt priority control register

3057	Interrupt Level Setting Registers n (IPC_ILRS7)	8	R/W	00h	6.4.3/73
3058	Interrupt Level Setting Registers n (IPC_ILRS8)	8	R/W	00h	6.4.3/73
3059	Interrupt Level Setting Registers n (IPC_ILRS9)	8	R/W	00h	6.4.3/73

#### **IPC** memory map

#### 6.4.1 IPC Status and Control Register (IPC\_SC)

This register contains status and control bits for the IPC.

Address: 3Eh base + 0h offset = 3Eh

#### **IPC\_SC** field descriptions

Field	Description
7 IPCE	Interrupt Priority Controller Enable
	This bit enables/disables the interrupt priority controller module.
	0 Disables IPCE. Interrupt generated from the interrupt source is passed directly to CPU without processing (bypass mode). The IPMPS register is not updated when the module is disabled.
	1 Enables IPCE and interrupt generated from the interrupt source is processed by IPC before passing to CPU.
6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page ...

#### MC9S08PL16S Reference Manual, Rev. 3, 06/2020

Field	Description
5 PSE	Pseudo Stack Empty
	This bit indicates that the pseudo stack has no valid information. This bit is automatically updated after each IPMPS register push or pull operation.
4 PSF	Pseudo Stack Full
	This bit indicates that the pseudo stack register IPMPS register is full. It is automatically updated after each IPMPS register push or pull operation. If additional interrupt is nested after this bit is set, the earliest interrupt mask value(IPM0[1:0]) stacked in IPMPS will be lost.
	0 IPMPS register is not full.
	1 IPMPS register is full.
3	Pull IPM from IPMPS
PULIPM	This bit pulls stacked IPM value from IPMPS register to IPM bits of IPCSC. Zeros are shifted into bit positions 1 and 0 of IPMPS.
	0 No operation.
	1 Writing 1 to this bit causes a 2-bit value from the interrupt priority mask pseudo stack register to be pulled to the IPM bits of IPCSC to restore the previous IPM value.
2	This field is reserved.
Reserved	This read-only field is reserved and always has the value 0.
IPM	Interrupt Priority Mask
	This field sets the mask for the interrupt priority control. If the interrupt priority controller is enabled, the interrupt source with an interrupt level (ILRxx) value that is greater than or equal to the value of IPM will be presented to the CPU. Writes to this field are allowed, but doing this will not push information to the IPMPS register. Writing IPM with PULIPM setting when IPCE is already set, the IPM will restore the value pulled from the IPMPS register, not the value written to the IPM register.

#### IPC\_SC field descriptions (continued)

#### 6.4.2 Interrupt Priority Mask Pseudo Stack Register (IPC\_IPMPS)

This register is used to store the previous interrupt priority mask level temporarily when the currently active interrupt is executed.

Bit	7	6	5	4	3	2	1	0
Read	IPM3		IPM2		IPM1		IPMO	
Write								
Reset	0	0	0	0	0	0	0	0

Field	Description
7–6 IPM3	Interrupt Priority Mask pseudo stack position 3
	This field is the pseudo stack register for IPM3. The most recent information is stored in IPM3.

Table continues on the next page ...

#### MC9S08PL16S Reference Manual, Rev. 3, 06/2020

Field	Description
5–4 IPM2	Interrupt Priority Mask pseudo stack position 2
	This field is the pseudo stack register for IPM2. The most recent information is stored in IPM2.
3–2 IPM1	Interrupt Priority Mask pseudo stack position 1
	This field is the pseudo stack register for IPM1. The most recent information is stored in IPM1.
IPM0	Interrupt Priority Mask pseudo stack position 0
	This field is the pseudo stack register for IPM0. The most recent information is stored in IPM0.

#### IPC\_IPMPS field descriptions (continued)

### 6.4.3 Interrupt Level Setting Registers n (IPC\_ILRSn)

This set of registers (ILRS0-ILRS9) contains the user specified interrupt level for each interrupt source, and indicates the number of the register (ILRSn is ILRS0 through ILRS9).

Address: 3Eh base + 3	3012h offset + (	(1d × i), where	i=0d to 9d
-----------------------	------------------	-----------------	------------

Bit	7	6	5	4	3	2	1	0
Read Write	IL	Rn3	ILF	Rn2	ILI	Rn1	ILF	Rn0
Reset	0	0	0	0	0	0	0	0

#### IPC\_ILRSn field descriptions

Field	Description
7–6 ILRn3	Interrupt Level Register for Source n*4+3
	This field sets the interrupt level for interrupt source n*4+3.
5–4 ILRn2	Interrupt Level Register for Source n*4+2
	This field sets the interrupt level for interrupt source n*4+2.
3–2 ILRn1	Interrupt Level Register for Source n*4+1
	This field sets the interrupt level for interrupt source n*4+1.
ILRn0	Interrupt Level Register for Source n*4+0
	This field sets the interrupt level for interrupt source n*4+0.

#### Interrupt priority control register

# Chapter 7 System control

# 7.1 System device identification (SDID)

This device is hard coded to the value 0x0046 in SDID registers.

# 7.2 Universally unique identification (UUID)

This device contains up to 64-bit UUID to identify each device in this family. The intent of UUID is to enable distributed systems to uniquely identify information without significant central coordination.

# 7.3 Reset and system initialization

Resetting the MCU provides a way to start processing from a set of known initial conditions. During reset, most control and status registers are forced to initial values and the program counter is loaded from the reset vector (0xFFFE:0xFFFF). On-chip peripheral modules are disabled and I/O pins are initially configured as general-purpose high-impedance inputs with disabled pullup devices. The CCR[I] bit is set to block maskable interrupts so that the user program has a chance to initialize the stack pointer (SP) and system control settings. SP is forced to 0x00FF at reset.

This device has the following sources for reset:

- Power-on reset (POR)
- Low-voltage detect (LVD)
- Watchdog (WDOG) timer
- Illegal opcode detect (ILOP)

- Background debug forced reset
- External reset pin (RESET)
- Internal clock source module reset (CLK)
- Flash Illegal Access (FILA)

Each of these sources, with the exception of the background debug forced reset, has an associated bit in the system reset status (SRS) register.

# 7.4 System options

# 7.4.1 BKGD pin enable

After POR, PTA4/FTM0CH1/ACMP0O/BKGD/MS/ pin functions as BKGD output. The SYS\_SOPT1[BKGDPE] bit must be set to enable the background debug mode pin enable function. When this bit is clear, this pin can function as PTA4, FTM0CH1 or ACMP0 output.

# 7.4.2 **RESET** pin enable

After POR reset, PTA5/IRQ/FTM0CH0/TCLK0/RESET\_b functions as RESET\_b. The SYS\_SOPT1[RSTPE] bit must be set to enable the reset functions. When this bit is clear, this pin can function as PTA5, IRQ, FTM0CH0, or TCLK0.

# 7.4.3 SCI0 pin reassignment

After reset, SCI0 module pinouts of RxD and TxD are mapped on PTB0 and PTB1, respectively. SYS\_SOPT1[SCI0PS] bit enables to reassign SCI0 pinouts on PTA2 and PTA3.

# 7.4.4 I2C pins reassignments

After POR reset, I2C module pinouts of SDA and SCL are mapped on PTA2 and PTA3. SYS\_SOPT1[IICPS] bit enables to reassign the I2C pinout pair on PTB6 and PTB7, or PTB2 and PTB3 respectively. All the I2C pins support pseudo open drain. When they act as IIC pins, the remote I2C level is limited to no more than MCU  $V_{DD}$ .

### 7.4.5 FTM0 channels pin reassignment

After reset, FTM0 channels pinouts of FTM0CH0 and FTM0CH1 are mapped on PTA0 and PTA1, respectively. SOPT3[FTM0PS] bit enables to reassign FTM0 channels pinouts on PTA5 and PTA4 (output only).

# 7.5 System interconnection

This device contains a set of system-level logics for module-to-module interconnection for flexible configuration. These interconnections provide the hardware trigger function between modules with least software configuration, which is ideal for infrared communication, serial communication baudrate detection, low-end motor control, metering clock calibration, and other general-purpose applications.

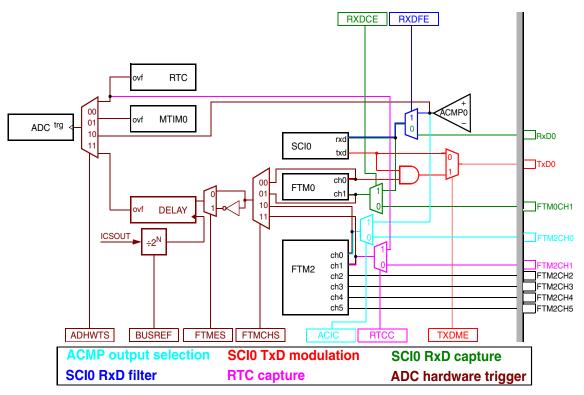

Figure 7-1. System interconnection diagram

# 7.5.1 ACMP output selection

When set, the SYS\_SOPT2[ACIC] bit enables the output of ACMP0 to connect to the FTM2CH0, the FTM2CH0 pin is released to other shared functions regardless of the configuration of FTM2 pin reassignment.

# 7.5.2 SCI0 TxD modulation

SCI0 TXD can be modulated by FTM0 channel 0 output. When SYS\_SOPT2[TXDME] bit is set, the TXD output is passed to an AND gate with FTM0 channel 0 output before mapping on TXD0 pinout. When this bit is clear, the TXD is directly mapped on the pinout. To enable IR modulation function, both FTM0CH0 and SCI must be active. The FTM0 counter modulo register specifies the period of the PWM, and the FTM0 channel 0 value register specifies the duty cycle of the PWM. Then, when TXDME bit is enabled, each data transmitted via TXD0 from SCI0 is modulated by the FTM0 channel 0 output, and the FTM0CH0 pin is released to other shared functions regardless of the configuration of FTM0 pin reassignment.

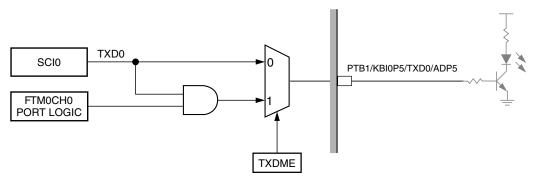

Figure 7-2. IR modulation diagram

# 7.5.3 SCI0 RxD capture

RxD0 pin is selectable connected to SCI0 module directly or tagged to FTM0 channel 1. When SYS\_SOPT2[RXDCE] bit is set, the RxD0 pin is connected to both SCI0 and FTM0 channel 1, and the FTM0CH1 pin is released to other shared functions regardless of the configuration of FTM0 pin reassignment. When this bit is clear, the RxD0 pin is connected to SCI0 only.

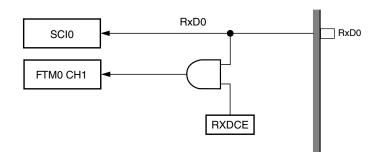

Figure 7-3. RxD0 capture function diagram

# 7.5.4 SCI0 RxD filter

When SYS\_SOPT2[RXDFE] bit is clear, the RxD0 pin is connected to SCI0 module directly. When this bit is set, the ACMP0 output is connected to the receive channel of SCI0. To enable RxD filter function, both SCI0 and ACMP0 must be active. If this function is active, the SCI0 external RxD0 pin is released to other shared functions regardless of the configuration of SCI0 pin reassignment. When SCI0 RxD capture function is active, the ACMP0 output is injected to FTM0CH1 as well.

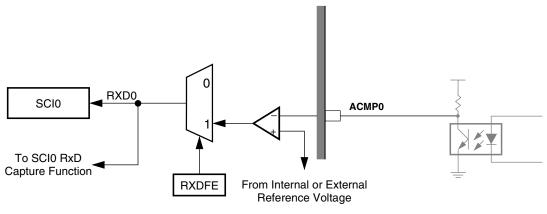

Figure 7-4. IR demodulation diagram

# 7.5.5 RTC capture

RTC overflow may be captured by FTM2 channel 1 by setting SYS\_SOPT2[RTCC] bit. When this bit is set, the RTC overflow is connected to FTM2 channel 1 for capture, the FTM2CH1 pin is released to other shared functions.

### 7.5.6 ADC hardware trigger

ADC module may initiate a conversion via a hardware trigger. RTC, MTIM0 overflow, ACMP0 output, FTM output with 8-bit programmable delay can be enabled as the hardware trigger for the ADC module by setting the SYS\_SOPT2[ADHWTS] bits. The following table shows the ADC hardware trigger setting.

ADHWT	ADC hardware trigger
0:0	RTC overflow
0:1	MTIM0 overflow
1:0	ACMP0 output
1:1	FTM0 channel 0/1 or FTM2 channel 0/1 output with 8-bit programmable delay and selectable edge

 Table 7-1.
 ADC hardware trigger setting

When ADC hardware trigger selects the output of FTM output, an 8-bit delay block will be enabled. This logic delays any trigger from FTM output with an 8-bit counter whose value is specified by SYS\_SOPT4[DELAY] bit. The reference clock to this module is the output of ICSOUT with selectable pre-divider specified by SYS\_SOPT3[BUSREF]. The FTM output trigger's effective edge (rising edge or falling edge) can be selected by SYS\_SOPT2[FTMES] bit.

When FTM runs in output compare mode or PWM mode, the channels output can be selected as ADC hardware trigger, and the selected channel pin is released to other shared functions. When FTM runs in input capture mode, no trigger is generated from FTM channels.

### NOTE

Do not set the FTM channel in input capture mode when this channel is selected as the ADC hardware trigger source, because of the input pin is not controlled by FTM modules.

# 7.6 FTM software controlled output

The FTM software controlled output feature is added to control the FTM0 and FTM2 channel output value by software. The SYS\_SOPT7[FTMxCHyOC] field enables or disables FTMx channel y software output function, and SYS\_SOPT8[FTMxCHyOCV] register controls the desired output value.

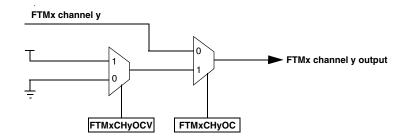

Figure 7-5. FTM software controlled output

# 7.7 System Control Registers

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
3000	System Reset Status Register (SYS_SRS)	8	R	82h	7.7.1/82

30FE	Universally Unique Identifier Register 7 (SYS_UUID7)	8	R	Undefined	7.7.25/102
30FF	Universally Unique Identifier Register 8 (SYS_UUID8)	8	R	Undefined	7.7.26/103

### 7.7.1 System Reset Status Register (SYS\_SRS)

This register includes read-only status flags to indicate the source of the most recent reset. When a debug host forces reset by writing 1 to the SYS\_SBDFR[BDFR] bit, none of the status bits in SRS will be set. The reset state of these bits depends on what caused the MCU to reset.

### NOTE

For PIN, WDOG, and ILOP, any of these reset sources that are active at the time of reset (not including POR or LVR) will cause the corresponding bit(s) to be set; bits corresponding to sources that are not active at the time of reset will be cleared.

### NOTE

The RESET values in the figure are values for power on reset; for other resets, the values depend on the trigger causes.

Address: 3000h base + 0h offset = 3000h

Bit	7	6	5	4	3	2	1	0
Read	POR	PIN	WCOP	ILOP	ILAD	LOC	LVD	FILA
Write								
Reset	1	0	0	0	0	0	1	0

#### SYS\_SRS field descriptions

Field	Description
7	Power-On Reset
POR	
	Reset was caused by the power-on detection logic. When the internal supply voltage was ramping up at the time, the low-voltage reset (LVR) status bit is also set to indicate that the reset occurred while the internal supply was below the LVR threshold.
	NOTE: This bit POR to 1, LVR to uncertain value and reset to 0 at any other conditions.
	0 Reset not caused by POR.
	1 POR caused reset.
6	External Reset Pin
PIN	
	Reset was caused by an active low level on the external reset pin.

Table continues on the next page ...

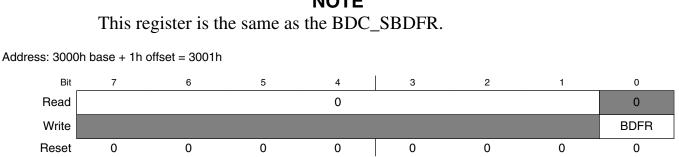

#### Chapter 7 System control

### SYS\_SRS field descriptions (continued)

Field	Description
	0 Reset not caused by external reset pin.
	1 Reset came from external reset pin.
5 WCOP	Windowed COP (WCOP)
	Reset was caused by the WCOP timer timing out. This reset source may be blocked by SYS_SOPT5[COPT] =00.
	0 Reset not caused by WCOP timeout.
	1 Reset caused by WCOP timeout.
4 ILOP	Illegal Opcode
	Reset was caused by an attempt to execute an unimplemented or illegal opcode. The STOP instruction is considered illegal if stop is disabled by STOPE = 0 in the SOPT register. The BGND instruction is considered illegal if active background mode is disabled by ENBDM = 0 in the BDCSC register.
	<ul><li>0 Reset not caused by an illegal opcode.</li><li>1 Reset caused by an illegal opcode.</li></ul>
3	Illegal Address
ILAD	Reset was caused by an attempt to access a illegal address. The illegal address is captured in illegal address register (ILLAH:ILLAL).
	0 Reset not caused by an illegal address.
	1 Reset caused by an illegal address.
2	Internal Clock Source Module Reset
LOC	Reset was caused by an ICS module reset.
	0 Reset not caused by ICS module.
	1 Reset caused by ICS module.
1 LVD	Low Voltage Detect
LVD	If the LVDRE bit is set in run mode or both LVDRE and LVDSE bits are set in stop mode, and the supply drops below the LVD trip voltage, an LVD reset will occur. This bit is also set by POR.
	NOTE: This bit reset to 1 on POR and LVR and reset to 0 on other reset.
	0 Reset not caused by LVD trip or POR.
	1 Reset caused by LVD trip or POR.
0 FILA	Flash Illegal Access
	Reset was caused by an flash illegal access.
	0 Reset not caused by an flash illegal access.
	1 Reset caused by an flash illegal access.

#### System Background Debug Force Reset Register (SYS SBDFR) 7.7.2

This register contains a single write-only control bit. A serial background command such as WRITE\_BYTE must be used to write to SYS\_SBDFR. Attempts to write this register from a user program are ignored. Reads always return 0x00.

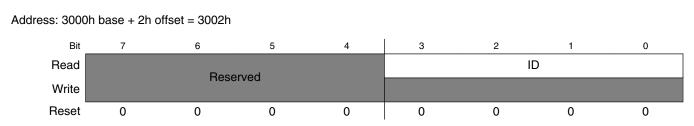

# NOTE

SYS\_SBDFR field descriptions

Field	Description
7–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 BDFR	Background Debug Force Reset A serial background command such as WRITE_BYTE may be used to allow an external debug host to
	force a target system reset. Writing logic 1 to this bit forces an MCU reset. This bit cannot be written from a user program.
	<b>NOTE:</b> BDFR is writable only through serial background debug commands, not from user programs.

#### System Device Identification Register: High (SYS\_SDIDH) 7.7.3

This read-only register, together with SYS\_SDIDL, is included so that host development systems can identify the HCS08 derivative and revision number. This allows the development software to recognize where specific memory blocks, registers, and control bits are located in a target MCU.

#### **Chapter 7 System control**

#### SYS\_SDIDH field descriptions

Field	Description
7–4 Reserved	This field is reserved.
	Part Identification Number These bits, together with the SYS_SDIDL, indicate part identification number. Each derivative in the HCS08 family has a unique identification number. This device is hard coded to the value 0x46.

### 7.7.4 System Device Identification Register: Low (SYS\_SDIDL)

This read-only register, together with SYS\_SDIDH, is included so host development systems can identify the HCS08 derivative and revision number. This allows the development software to recognize where specific memory blocks, registers, and control bits are located in a target MCU.

#### Address: 3000h base + 3h offset = 3003h

Bit	7	6	5	4	3	2	1	0
Read				I	D			
Write								
Reset	0	1	0	0	0	1	1	0

#### SYS\_SDIDL field descriptions

Field	Description
ID	Part Identification Number
	These bits, together with the SYS_SDIDH, indicate part identification number. Each derivative in the HCS08 family has a unique identification number. This device is hard coded to the value 0x46.

### 7.7.5 System Options Register 1 (SYS\_SOPT1)

Address: 3000h base + 4h offset = 3004h

Bit	7	6	5	4	3	2	1	0
Read Write	SCIOPS	IIC	PS	0	BKGDPE	RSTPE	FWAKE	STOPE
Reset	0	0	0	0	1	1	0	0

#### SYS\_SOPT1 field descriptions

Field	Description
7 SCI0PS	SCI0 Pin Select
3010F3	This write-once bit selects the SCI0 pinouts.

Table continues on the next page ...

SYS	_SOPT1	field	descriptions	(continued)
-----	--------	-------	--------------	-------------

Field	Description
	0 SCI0 RxD and TxD are mapped on PTB0 and PTB1.
	1 SCI0 RxD and TxD are mapped on PTA2 and PTA3.
6–5 IICPS	IIC Port Pin Select
	This write-once bit selects the IIC port pins.
	00 IIC SCL and SDA are mapped on PTA3 and PTA2, respectively.
	01 IIC SCL and SDA are mapped on PTB7 and PTB6, respectively.
	10 IIC SCL and SDA are mapped on PTB3 and PTB2, respectively.
	11 Reserved.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 BKGDPE	Background Debug Mode Pin Enable
	This write-once bit when set enables the PTA4/FTM0CH1O/ACMP0O/BKGD/MS pin to function as BKGD/MS. When clear, the pin functions as output only PTA4. This pin defaults to the BKGD/MS function following any MCU reset.
	0 PTA4/FTM0CH1O/ACMP0O/BKGD/MS as PTA4, FTM0CH1O or ACMPOO function.
	1 PTA4/FTM0CH1O/ACMP0O/BKGD/MS as BKGD function.
2 RSTPE	RESET Pin Enable
	This write-once bit can be written after any reset. When RSTPE is set, the PTA5/IRQ/FTM0CH0/TCLK0/ RESET_b pin functions as RESET. When clear, the pin functions as one of its alternative functions. This pin defaults to RESET following an MCU POR. Other resets will not affect this bit. When RSTPE is set, an internal pullup device on RESET is enabled.
	0 PTA5/IRQ/FTM0CH0/TCLK0/RESET_b pin functions as PTA5, IRQ, FTM0CH0 or TCLK0.
	1 PTA5/IRQ/FTM0CH0/TCLK0/RESET_b pin functions as RESET.
1	Fast Wakeup Enable
FWAKE	This write once bit can set CPU wakeup without any interrupt subroutine serviced. This action saved more than 11 cycles(whole interrupt subroutine time). After wake up CPU continue the address before wait or stop.
	<b>NOTE:</b> When FWAKE is set, user should avoid generating interrupt 0-8 bus clock cycles after issuing the stop instruction, or the MCU may stuck at stop3 mode and cannot wake up by interrupts.
	0 CPU wakes up as normal.
	1 CPU wakes up without any interrupt subroutine serviced.
0 STOPE	Stop Mode Enable
STOLE	This write-once bit defaults to 0 after reset, which disables stop mode. If stop mode is disabled and a user program attempts to execute a STOP instruction, an illegal opcode reset occurs.
	0 Stop mode disabled.

### 7.7.6 System Options Register 2 (SYS\_SOPT2)

This register may be read/write at any time. SYS\_SOPT2 should be written during the user's reset initialization program to set the desired controls even if the desired settings are the same as the reset settings.

Address: 3000h base + 5h offset = 3005h

Bit	7	6	5	4	3	2	1	0
Read Write	TXDME	FTMES	RXDFE	RXDCE	ACIC	RTCC	ADH	WTS
Reset	0	0	0	0	0	0	0	0

Field	Description
7	SCI0 TxD Modulation Select
TXDME	This hit enables the SOIO TyD sytewit moduleted by FTM0 shannel 0
	This bit enables the SCI0 TxD output modulated by FTM0 channel 0.
	0 TxD0 output is connected to pinout directly.
	1 TxD0 output is modulated by FTM0 channel 0 before mapped to pinout.
6	FTM Edge Select
FTMES	This bit selects the effective FTM output edge to trigger ADC.
	0 Rising edge.
	1 Falling edge.
5	SCI0 RxD Filter Select
RXDFE	This bit apphas the SCIO ByD input filtered by ACMBO. When this function is apphled, any signal tagge
	This bit enables the SCI0 RxD input filtered by ACMP0. When this function is enabled, any signal tagger with ACMP0 inputs can be regarded SCI0.
	0 RXD0 input signal is connected to SCI0 module directly.
	1 RXD0 input signal is filtered by ACMP0, then injected to SCI0.
4	SCI0 RxD Capture Select
RXDCE	This bit enables the SCI0 RxD is captured by FTM0 channel 1.
	0 RXD0 input signal is connected to SCI0 module only.
	1 RXD0 input signal is connected to SCI0 module and FTM0 channel 1.
3	Analog Comparator to Input Capture Enable
ACIC	This bit connects the output of ACMP0 to FTM2 input channel 0.
	0 ACMP0 output not connected to FTM2 input channel 0.
	1 ACMP0 output connected to FTM2 input channel 0.
2	Real-Time Counter Capture
RTCC	This bit allows the Real-time Counter (RTC) overflow to be captured by FTM2 channel 1.

#### SYS\_SOPT2 field descriptions

Table continues on the next page...

Field	Description						
	0 RTC overflow is not connected to FTM2 input channel 1.						
	1 RTC overflow is connected to FTM2 input channel 1.						
ADHWTS	ADC Hardware Trigger Source						
	These bits select the ADC hardware trigger source. All trigger sources start ADC conversion on rising edge.						
	00 RTC overflow as the ADC hardware trigger.						
	01 MTIM0 overflow as the ADC hardware trigger.						
	10 ACMP0 output as the ADC hardware trigger.						
	11 FTM0 channel 0/1 or FTM2 channel 0/1 output with 8-bit programmable delay and selectable edge.

Field	Description				
7	FTM2 channel 5 Output Control				
FTM2CH5OC	This bit enables the software output control function for FTM2 channel 5 output.				
	0 Software output control function for FTM2 channel 5 is disabled.				
	1 Software output control function for FTM2 channel 5 is enabled.				
6 FTM2CH4OC	FTM2 channel 4 Output Control				
	This bit enables the software output control function for FTM2 channel 4 output.				
	0 Software output control function for FTM2 channel 4 is disabled.				
	1 Software output control function for FTM2 channel 4 is enabled.				
5 FTM2CH3OC	FTM2 channel 3 Output Control				
FTWZGTISOC	This bit enables the software output control function for FTM2 channel 3 output.				
	0 Software output control function for FTM2 channel 3 is disabled.				
	1 Software output control function for FTM2 channel 3 is enabled.				
4 FTM2CH2OC	FTM2 channel 2 Output Control				
	This bit enables the software output control function for FTM2 channel 2 output.				
	-				

Table continues on the next page...

Field	Description					
	0 Software output control function for FTM2 channel 2 is disabled.					
	1 Software output control function for FTM2 channel 2 is enabled.					
3	FTM2 channel 1 Output Control					
FTM2CH1OC	This bit enables the software output control function for FTM2 channel 1 output.					
	0 Software output control function for FTM2 channel 1 is disabled.					
	1 Software output control function for FTM2 channel 1 is enabled.					
2 FTM2CH0OC	FTM2 channel 0 Output Control					
	This bit enables the software output control function for FTM2 channel 0 output.					
	0 Software output control function for FTM2 channel 0 is disabled.					
	1 Software output control function for FTM2 channel 0 is enabled.					
1	FTM0 channel 1 Output Control					
FTM0CH1OC	This bit enables the software output control function for FTM0 channel 1 output.					
	0 Software output control function for FTM0 channel 1 is disabled.					
	1 Software output control function for FTM0 channel 1 is enabled.					
0 FTM0CH0OC	FTM0 channel 0 Output Control					
	This bit enables the software output control function for FTM0 channel 0 output.					
	0 Software output control function for FTM0 channel 0 is disabled.					
	1 Software output control function for FTM0 channel 0 is enabled.

7 FTM2CH5OCV	2 channel 5 Output Control Value					
	This bit selects the software output control value for FTM2 channel 5 output.					
	0 Software output control value for FTM2 channel 5 is 0.					
	1 Software output control value for FTM2 channel 5 is 1.					

Table continues on the next page...

#### SYS\_SOPT8 field descriptions (continued)

Field	Description
6	FTM2 channel 4 Output Control Value
FTM2CH4OCV	This bit selects the software output control value for FTM2 channel 4 output.
	0 Software output control value for FTM2 channel 4 is 0.
	1 Software output control value for FTM2 channel 4 is 1.
5 FTM2CH3OCV	FTM2 channel 3 Output Control Value
	This bit selects the software output control value for FTM2 channel 3 output.
	0 Software output control value for FTM2 channel 3 is 0.
	1 Software output control value for FTM2 channel 3 is 1.
4 FTM2CH2OCV	FTM2 channel 2 Output Control Value
	This bit selects the software output control value for FTM2 channel 2 output.
	0 Software output control value for FTM2 channel 2 is 0.
	1 Software output control value for FTM2 channel 2 is 1.
3	FTM2 channel 1 Output Control Value
FTM2CH1OCV	This bit selects the software output control value for FTM2 channel 1 output.
	0 Software output control value for FTM2 channel 1 is 0.
	1 Software output control value for FTM2 channel 1 is 1.
2 FTM2CH0OCV	FTM2 channel 0 Output Control Value
	This bit selects the software output control value for FTM2 channel 0 output.
	0 Software output control value for FTM2 channel 0 is 0.
	1 Software output control value for FTM2 channel 0 is 1.
1 FTM0CH1OCV	FTM0 channel 1 Output Control Value
	This bit selects the software output control value for FTM0 channel 1 output.
	0 Software output control value for FTM0 channel 1 is 0.
	1 Software output control value for FTM0 channel 1 is 1.
0 FTM0CH0OCV	FTM0 channel 0 Output Control Value
	This bit selects the software output control value for FTM0 channel 0 output.
	0 Software output control value for FTM0 channel 0 is 0.
	1 Software output control value for FTM0 channel 0 is 1.

### 7.7.13 System Clock Gating Control 1 Register (SYS\_SCGC1)

This high page register contains control bits to enable or disable the bus clock to the FTMs, MTIM, and RTC modules. Gating off the clocks to unused peripherals is used to reduce the MCU's run and wait currents.

### NOTE

User software must disable the peripheral before disabling the clocks to the peripheral. When clocks are re-enabled to a peripheral, the peripheral registers need to be re-initialized by user software.

Address: 3000h base + Ch offset = 300Ch

### 7.7.17 Illegal Address Register: High (SYS\_ILLAH)

The SYS\_ILLAH is a read-only register containing the high 8-bit of the illegal address of ILAD reset.

Address: 3000h base + 4Ah offset = 304Ah

\* Notes:

• x = Undefined at reset.

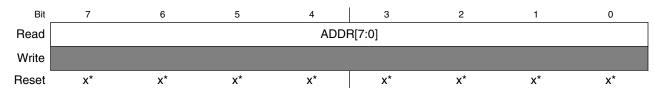

### SYS\_ILLAH field descriptions

Field	Description
ADDR[15:8]	High 8-bit of illegal address
	<b>NOTE:</b> For ILAD, it reset to the high 8-bit of the illegal address; in other cases, the reset to values are undetermined.

### 7.7.18 Illegal Address Register: Low (SYS\_ILLAL)

The SYS\_ILLAL is a read-only register containing the low 8-bit of the illegal address of ILAD reset.

Address: 3000h base + 4Bh offset = 304Bh

\* Notes:

• x = Undefined at reset.

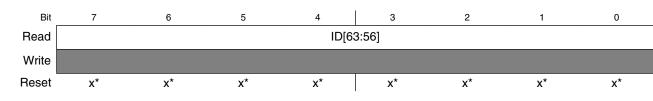

#### SYS\_ILLAL field descriptions

Field	Description
ADDR[7:0]	Low 8-bit of illegal address
	<b>NOTE:</b> For ILAD, it resets to the low 8-bit of the illegal address; in other cases, the reset to values are undetermined.

### 7.7.19 Universally Unique Identifier Register 1 (SYS\_UUID1)

The read-only SYS\_UUIDx registers contain a series of 64-bit number to identify the unique device in the family.

Address: 3000h base + F8h offset = 30F8h

\* Notes:

• x = Undefined at reset.

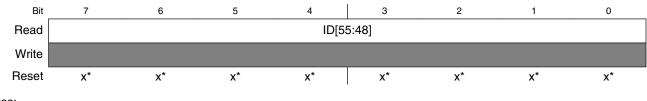

#### SYS\_UUID1 field descriptions

Field	Description
ID[63:56]	Universally Unique Identifier

### 7.7.20 Universally Unique Identifier Register 2 (SYS\_UUID2)

The read-only SYS\_UUIDx registers contain a series of 63-bit number to identify the unique device in the family.

Address: 3000h base + F9h offset = 30F9h

\* Notes:

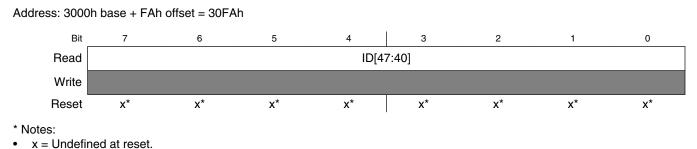

• x = Undefined at reset.

#### SYS\_UUID2 field descriptions

Field	Description
ID[55:48]	Universally Unique Identifier

### 7.7.21 Universally Unique Identifier Register 3 (SYS\_UUID3)

The read-only SYS\_UUIDx registers contain a series of 63-bit number to identify the unique device in the family.

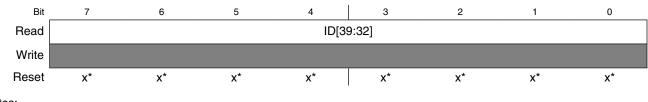

### SYS\_UUID3 field descriptions

Field	Description
ID[47:40]	Universally Unique Identifier

### 7.7.22 Universally Unique Identifier Register 4 (SYS\_UUID4)

The read-only SYS\_UUIDx registers contain a series of 63-bit number to identify the unique device in the family.

Address: 3000h base + FBh offset = 30FBh

\* Notes:

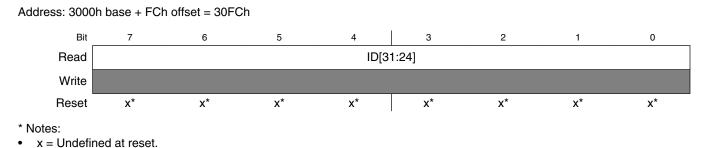

• x = Undefined at reset.

#### SYS\_UUID4 field descriptions

Field	Description
ID[39:32]	Universally Unique Identifier

### 7.7.23 Universally Unique Identifier Register 5 (SYS\_UUID5)

The read-only SYS\_UUIDx registers contain a series of 64-bit number to identify the unique device in the family.

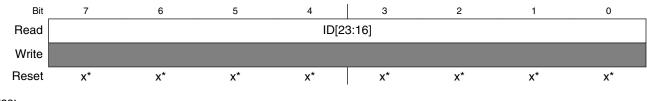

### SYS\_UUID5 field descriptions

Field	Description
ID[31:24]	Universally Unique Identifier

### 7.7.24 Universally Unique Identifier Register 6 (SYS\_UUID6)

The read-only SYS\_UUIDx registers contain a series of 64-bit number to identify the unique device in the family.

Address: 3000h base + FDh offset = 30FDh

\* Notes:

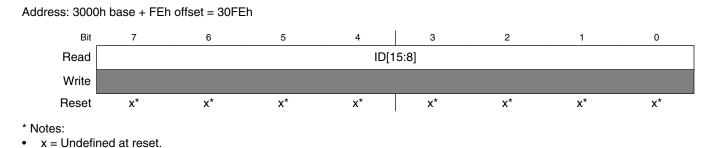

• x = Undefined at reset.

#### SYS\_UUID6 field descriptions

Field	Description
ID[23:16]	Universally Unique Identifier

### 7.7.25 Universally Unique Identifier Register 7 (SYS\_UUID7)

The read-only SYS\_UUIDx registers contain a series of 64-bit number to identify the unique device in the family.

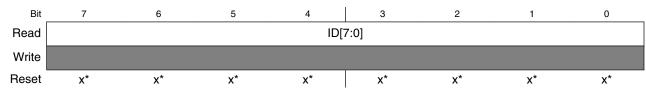

SYS\_UUID7 field descriptions

Field	Description
ID[15:8]	Universally Unique Identifier

### 7.7.26 Universally Unique Identifier Register 8 (SYS\_UUID8)

The read-only SYS\_UUIDx registers contain a series of 64-bit number to identify the unique device in the family.

Address: 3000h base + FFh offset = 30FFh

\* Notes:

• x = Undefined at reset.

#### SYS\_UUID8 field descriptions

Field	Description
ID[7:0]	Universally Unique Identifier

# Chapter 8 Clock management

# 8.1 Clock module

These series contain the following on-chip clock sources:

- Internal clock source (ICS) module The main clock source generator providing bus clock and other reference clocks to peripherals
- External oscillator (XOSC) module The external oscillator providing reference clock to internal clock source (ICS), the real-time clock counter clock module (RTC) and other MCU sub-systems.
- Low-power oscillator (LPO) module The on-chip low-power oscillator providing 1 kHz reference clock to RTC and watchdog (WCOP).

### NOTE

For this device, the system clock is the bus clock.

# 8.2 System clock distribution

The following figure shows a simplified clock connection diagram.

System clock distribution

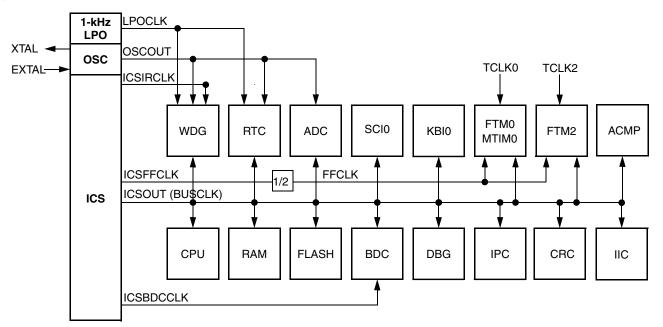

Figure 8-1. System clock distribution diagram

The clock system supplies:

- ICSOUT(BUSCLK) This clock source is used as the bus clock which is the reference to CPU and all peripherals. Control bits in the ICS control registers determine which of the following clock sources is connected:
  - Internal reference clock
  - External reference clock
  - Frequency-locked loop (FLL) output
- ICSBDCCLK This clock source is derived from the digitally controlled oscillator (DCO) of the ICS when the ICS is configured to run off of the internal or external reference clock. Development tools can select this internal self-clocked source (16 MHz) to speed up BDC communications in systems where the bus clock is slow.
- ICSIRCLK This is the internal reference clock and can be selected as the clock source to the WCOP and RTC modules.
- ICSFFCLK This is the reference clock of the FLL. Its frequency is determined by the setting of the ICS. ICSFFCLK is also used to generate the fixed frequency clock (FFCLK).
- FFCLK This is the fixed frequency clock which can be selected as the clock source to the FTM and MTIM modules. It is generated by the ICSFFCLK after being synchronized to the bus clock, so the frequency of FFCLK is half of ICSFFCLK..

- LPOCLK This clock is generated from an internal low power oscillator (≈1 kHz) that is completely independent of the ICS module. The LPOCLK can be selected as the clock source to the RTC or WDOG modules.
- OSCOUT This is the direct output of the external oscillator module and can be selected as the clock source for RTC, WDOG and ADC.
- TCLK0 This is an optional external clock source for the FTM0 and MTIM0 modules. The TCLK0 must be limited to 1/4th frequency of the bus clock for synchronization.
- TCLK2 This is an optional external clock source for the FTM2 module. The TCLK2 must be limited to 1/4th frequency of the bus clock for synchronization.

### NOTE

Some tools like ProcessorExpert or USB Multilink may use flash memory location, such as 0xFF6F and/or 0xFF6E, to store the temporary trim value.

### 8.3 Internal clock source (ICS)

The internal clock source (ICS) module provides clock source options for the MCU. The module contains a frequency-locked loop (FLL) as a clock source that is controllable by an internal or external reference clock. The module can provide this FLL clock or the internal reference clock as a source for the MCU system clock, ICSOUT.

Whichever clock source is chosen, ICSOUT is the output from a bus clock divider (BDIV), which allows a lower clock frequency to be derived.

Key features of the ICS module are:

- Frequency-locked loop (FLL) is trimmable for accuracy
- Internal or external reference clocks can be used to control the FLL
- Reference divider is provided for external clock
- Internal reference clock has nine trim bits available
- Internal or external reference clocks can be selected as the clock source for the MCU
- Whichever clock is selected as the source can be divided down by 1, 2, 4, 8, 16, 32, 64 or 128
- FLL Engaged Internal mode is automatically selected out of reset

- A constant divide by 2 of the DCO output that can be select as BDC clock.
- Digitally-controlled oscillator (DCO) optimized for 32 MHz to 40 MHz frequency range
- FLL lock detector and external clock monitor
  - FLL lock detector with interrupt capability
  - External reference clock monitor with reset capability

# 8.4 Oscillator (OSC)

The OSC module provides the clock source for the MCU. The OSC module, in conjunction with an external crystal or resonator, generates a clock for the MCU that can be used as reference clock or bus clock.

Key features of the OSC module are:

- Supports 32 kHz crystals (low range mode)
- Supports 4–20 MHz crystals and resonators (high range mode)
- Automatic gain control (AGC) to optimize power consumption in both frequency ranges using low-power mode (low gain mode)
- High gain option in both frequency ranges: 32 kHz, 4–20 MHz
- Voltage and frequency filtering to guarantee clock frequency and stability
- Supports to be enabled by ICS.

# 8.5 Peripheral clock gating

This device includes a clock gating system to manage the bus clock sources to the individual peripherals. Using this system, the user can enable or disable the bus clock to each of the peripherals at the clock source, eliminating unnecessary clocks to peripherals that are not in use, thereby reducing the overall run and wait mode currents.

Out of reset, all peripheral clocks will be enabled. For lowest possible run or wait currents, user software should disable the clock source to any peripheral not in use. The actual clock will be enabled or disabled immediately following the write to the Clock Gating Control registers (SYS\_SCGC1, SYS\_SCGC2, SYS\_SCGC3, and SYS\_SCGC4). Any peripheral with a gated clock can not be used unless its clock is enabled. Writing to the registers of a peripheral with a disabled clock has no effect.

### Note

User software must disable the peripheral before disabling the clocks to the peripheral. When clocks to a peripheral are reenabled, the peripheral registers need to be re-initialized by user software.

In stop modes, the bus clock is disabled for all gated peripherals, regardless of the setting in SYS\_SCGCx (x=1,2,3,4) registers.

# Chapter 9 Central processor unit

## 9.1 Introduction

This section provides summary information about the registers, addressing modes, special operations, instructions and exceptions processing of the HCS08 V6 CPU.

The HCS08 V6 CPU is fully source- and object-code-compatible with the HCS08 CPU.

### 9.1.1 Features

Features of the HCS08 V6 CPU include:

- Object code fully upward-compatible with M68HC05 and M68HC08 families
- 16-bit stack pointer (any size stack anywhere in 64 KB CPU address space)
- 16-bit index register (H:X) with powerful indexed addressing modes
- 8-bit accumulator (A)
- Many instructions treat X as a second general-purpose 8-bit register
- Seven addressing modes:
  - Inherent Operands in internal registers
  - Relative 8-bit signed offset to branch destination
  - Immediate Operand in next object code byte(s)
  - Direct Operand in memory at 0x0000–0x00FF
  - Extended Operand anywhere in 64-Kbyte address space

- Indexed relative to H:X Five submodes including auto increment
- Indexed relative to SP Improves C efficiency dramatically
- Memory-to-memory data move instructions with four address mode combinations
- Overflow, half-carry, negative, zero, and carry condition codes support conditional branching on the results of signed, unsigned, and binary-coded decimal (BCD) operations
- Efficient bit manipulation instructions
- STOP and WAIT instructions to invoke low-power operating modes

# 9.2 Programmer's Model and CPU Registers

Figure 9-1 shows the five CPU registers. CPU registers are not part of the memory map.

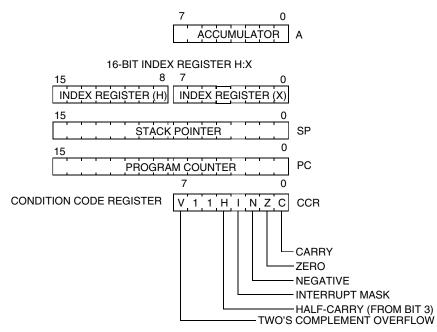

Figure 9-1. CPU Registers

# 9.2.1 Accumulator (A)

The A accumulator is a general-purpose 8-bit register. One input operand from the arithmetic logic unit (ALU) is connected to the accumulator, and the ALU results are often stored into the A accumulator after arithmetic and logical operations. The

accumulator can be loaded from memory using various addressing modes to specify the address where the loaded data comes from, or the contents of A can be stored to memory using various addressing modes to specify the address where data from A will be stored.

Reset has no effect on the contents of the A accumulator.

# 9.2.2 Index Register (H:X)

This 16-bit register is actually two separate 8-bit registers (H and X), which often work together as a 16-bit address pointer where H holds the upper byte of an address and X holds the lower byte of the address. All indexed addressing mode instructions use the full 16-bit value in H:X as an index reference pointer; however, for compatibility with the earlier M68HC05 family, some instructions operate only on the low-order 8-bit half (X).

Many instructions treat X as a second general-purpose 8-bit register that can be used to hold 8-bit data values. X can be cleared, incremented, decremented, complemented, negated, shifted, or rotated. Transfer instructions allow data to be transferred from A or transferred to A where arithmetic and logical operations can then be performed.

For compatibility with the earlier M68HC05 family, H is forced to 0x00 during reset. Reset has no effect on the contents of X.

# 9.2.3 Stack Pointer (SP)

This 16-bit address pointer register points at the next available location on the automatic last-in-first-out (LIFO) stack. The stack may be located anywhere in the 64 KB address space that has RAM, and can be any size up to the amount of available RAM. The stack is used to automatically save the return address for subroutine calls, the return address and CPU registers during interrupts, and for local variables. The AIS (add immediate to stack pointer) instruction adds an 8-bit signed immediate value to SP. This is most often used to allocate or deallocate space for local variables on the stack.

SP is forced to 0x00FF at reset for compatibility with the earlier M68HC05 family. HCS08 V6 programs normally change the value in SP to the address of the last location (highest address) in on-chip RAM during reset initialization to free up direct page RAM (from the end of the on-chip registers to 0x00FF).

The RSP (reset stack pointer) instruction was included for compatibility with the M68HC05 family and is seldom used in new HCS08 V6 programs because it affects only the low-order half of the stack pointer.

## 9.2.4 Program Counter (PC)

The program counter is a 16-bit register that contains the address of the next instruction or operand to be fetched.

During normal program execution, the program counter automatically increments to the next sequential memory location every time an instruction or operand is fetched. Jump, branch, interrupt, and return operations load the program counter with an address other than that of the next sequential location. This is called a change-of-flow.

During reset, the program counter is loaded with the reset vector that is located at 0xFFFE and 0xFFFF. The vector stored there is the address of the first instruction that will be executed after exiting the reset state.

## 9.2.5 Condition Code Register (CCR)

The 8-bit condition code register contains the interrupt mask (I) and five flags that indicate the results of the instruction just executed. Bits 6 and 5 are set permanently to 1. The following paragraphs describe the functions of the condition code bits in general terms.

Field	Description
7 V	<b>Two's Complement Overflow Flag</b> — The CPU sets the overflow flag when a two's complement overflow occurs. The signed branch instructions BGT, BGE, BLE, and BLT use the overflow flag.
-	0 No overflow
	1 Overflow
4 H	Half-Carry Flag — The CPU sets the half-carry flag when a carry occurs between accumulator bits 3 and 4 during an add-without-carry (ADD) or add-with-carry (ADC) operation. The half-carry flag is required for binary-coded decimal (BCD) arithmetic operations. The DAA instruction uses the states of the H and C condition code bits to automatically add a correction value to the result from a previous ADD or ADC on BCD operands to correct the result to a valid BCD value.
	0 No carry between bits 3 and 4
	1 Carry between bits 3 and 4
3 I	<b>Interrupt Mask Bit</b> — When the interrupt mask is set, all maskable CPU interrupts are disabled. CPU interrupts are enabled when the interrupt mask is cleared. When a CPU interrupt occurs, the interrupt mask is set automatically after the CPU registers are saved on the stack, but before the first instruction of the interrupt service routine is executed.
	Interrupts are not recognized at the instruction boundary after any instruction that clears I (CLI or TAP). This ensures that the next instruction after a CLI or TAP will always be executed without the possibility of an intervening interrupt, provided I was set.
	0 Interrupts enabled
	Table continues on the next page

Table 9-1. CCR Register Field Descriptions

MC9S08PL16S Reference Manual, Rev. 3, 06/2020

Field	Description
	1 Interrupts disabled
2 N	<b>Negative Flag</b> — The CPU sets the negative flag when an arithmetic operation, logic operation, or data manipulation produces a negative result, setting bit 7 of the result. Simply loading or storing an 8-bit or 16-bit value causes N to be set if the most significant bit of the loaded or stored value was 1.
	0 Non-negative result
	1 Negative result
1	Zero Flag — The CPU sets the zero flag when an arithmetic operation, logic operation, or data
Z	manipulation produces a result of 0x00 or 0x0000. Simply loading or storing an 8-bit or 16-bit value causes Z to be set if the loaded or stored value was all 0s.
	0 Non-zero result
	1 Zero result
0	Carry/Borrow Flag — The CPU sets the carry/borrow flag when an addition operation produces a
с	carry out of bit 7 of the accumulator or when a subtraction operation requires a borrow. Some instructions — such as bit test and branch, shift, and rotate — also clear or set the carry/borrow flag.
	0 No carry out of bit 7
	1 Carry out of bit 7

Table 9-1. CCR Register Field Descriptions (continued)

## 9.3 Addressing Modes

Addressing modes define the way the CPU accesses operands and data. In the HCS08 V6, memory, status and control registers, and input/output (I/O) ports share a single 64 KB CPU address space. This arrangement means that the same instructions that access variables in RAM can also be used to access I/O and control registers or nonvolatile program space.

Some instructions use more than one addressing mode. For instance, move instructions use one addressing mode to specify the source operand and a second addressing mode to specify the destination address. Instructions such as BRCLR, BRSET, CBEQ, and DBNZ use one addressing mode to specify the location of an operand for a test and then use relative addressing mode to specify the branch destination address when the tested condition is true. For BRCLR, BRSET, CBEQ, and DBNZ, the addressing mode listed in the instruction set tables is the addressing mode needed to access the operand to be tested, and relative addressing mode is implied for the branch destination.

Every addressing mode, except inherent, generates a 16-bit effective address. The effective address is the address of the memory location that the instruction acts on. Effective address computations do not require extra execution cycles. The HCS08 V6 CPU uses the 16 addressing modes described in the following sections.

### 9.3.1 Inherent Addressing Mode (INH)

In this addressing mode, instructions either have no operands or all operands are in internal CPU registers. In either case, the CPU does not need to access any memory locations to complete the instruction. Examples:

NOP ;this instruction has no operands CLRA ;operand is a CPU register

## 9.3.2 Relative Addressing Mode (REL)

Relative addressing mode is used to specify the destination location for branch instructions. A signed two's complement byte offset value is located in the memory location immediately following the opcode. The offset gives a branching range of -128 to +127 bytes. In most assemblers, the programmer does not need to calculate the offset, because the assembler determines the proper offset and verifies that it is within the span of the branch.

During program execution, if a branch condition is true, the signed offset is signextended to a 16-bit value and is added to the current contents of the program counter, which causes program execution to continue at the branch destination address. If a branch condition is false, the CPU executes the next instruction.

### 9.3.3 Immediate Addressing Mode (IMM)

The operand for instructions with the immediate addressing mode is contained in the byte(s) immediately following the opcode. The byte or bytes that follow the opcode are the value of the statement rather than the address of the value. The pound symbol (#) is used to indicate an immediate addressing mode operand. One very common programming error is to accidentally omit the # symbol. This causes the assembler to misinterpret the following expression as an address rather than explicitly provided data. For example LDA #\$55 means to load the immediate value \$55 into the accumulator, while LDA \$55 means to load the value from address \$0055 into the accumulator. Without the # symbol, the instruction is erroneously interpreted as a direct addressing instruction.

Example:

LDA #\$55 CPHX #\$FFFF LDHX #\$67 The size of the immediate operand is implied by the instruction context. In the third example, the instruction implies a 16-bit immediate value, but only an 8-bit value is supplied. In this case the assembler generates the 16-bit value \$0067 because the CPU expects a 16-bit value in the instruction stream.

## 9.3.4 Direct Addressing Mode (DIR)

This addressing mode is sometimes called zero-page addressing because it accesses operands in the address range \$0000 through \$00FF. Since these addresses always begin with \$00, only the low byte of the address needs to be included in the instruction, which saves program space and execution time. A system can be optimized by placing the most commonly accessed data in this area of memory. The low byte of the operand address is supplied with the instruction and the high byte of the address is assumed to be zero.

Examples:

LDA \$55

The value \$55 is taken to be the low byte of an address in the range \$0000 through \$00FF. The high byte of the address is assumed to be zero. During execution, the CPU combines the value \$55 from the instruction with the assumed value of \$00 to form the address \$0055, which is then used to access the data to be loaded into accumulator.

LDHX \$20

In this example, the value \$20 is combined with the assumed value of \$00 to form the address \$0020. Since the LDHX instruction requires a 16-bit value, a 16-bit word of data is read from addresses \$0020 and \$0021. After execution, the H:X index register has the value from address \$0020 in its high byte and the value from address \$0021 in its low byte. The same happens for CPHX and STHX.

BRSET 0,\$80,foo

In this example, direct addressing is used to access the operand and relative addressing is used to identify the destination address of a branch, in case the branch-taken conditions are met. This is also the case for BRCLR.

### 9.3.5 Extended Addressing Mode (EXT)

In extended addressing, the full 16-bit address of the memory location to be operated on is provided in the instruction. Extended addressing can access any location in the 64 KB memory map.

Example:

Addressing	Modes
LDA	\$F03B

This instruction uses extended addressing because \$F03B is above the zero page. In most assemblers, the programmer does not need to specify whether an instruction is direct or extended. The assembler automatically selects the shortest form of the instruction.

### 9.3.6 Indexed Addressing Mode

Indexed addressing mode has seven variations, including five that use the 16-bit H:X index register pair and two that use the stack pointer as the base reference.

### 9.3.6.1 Indexed, No Offset (IX)

Instructions using the indexed, no offset addressing mode are one-byte instructions that can access data with variable addresses. The X (Index register low byte) register contains the low byte of the conditional address of the operand and the H (Index register high byte) register contains the high byte of the address.

Indexed, no offset instructions can move a pointer through a table or hold the address of a frequently used RAM or input/output (I/O) location.

### 9.3.6.2 Indexed, No Offset with Post Increment (IX+)

Instructions using the indexed, no offset with post increment addressing mode are twobyte instructions that address the operands and then increment the Index register (H:X). The X (Index register low byte) register contains the low byte of the conditional address of the operand and the H (Index register high byte) register contains the high byte of the address. This addressing mode is usually used for table searches. MOV and CBEQ instructions use this addressing mode as well.

# 9.3.6.3 Indexed, 8-Bit Offset (IX1)

Indexed with 8-bit offset instructions are two-byte instructions that can access data with a variable address. The CPU adds the unsigned bytes in the H:X register to the unsigned byte immediately following the opcode. The sum is the effective address.

Indexed, 8-bit offset instructions are useful in selecting the k-th element in an n-element table. The table can begin anywhere and can extend as far as the address map allows. The k value would typically be in H:X, and the address of the beginning of the table would be

in the byte following the opcode. Using H:X in this way, this addressing mode is limited to the first 256 addresses in memory. Tables can be located anywhere in the address map when H:X is used as the base address, and the byte following the opcode is the offset.

### 9.3.6.4 Indexed, 8-Bit Offset with Post Increment (IX1+)

Indexed, 8-bit offset with post-increment instructions are three-byte instructions that access the operands with variable addresses, then increment H:X. The CPU adds the unsigned bytes in the H:X register to the byte immediately following the opcode. The sum is the effective address. This addressing mode is generally used for table searches. This addressing mode is used for CBEQ instruction.

### 9.3.6.5 Indexed, 16-Bit Offset (IX2)

Indexed, 16-bit offset instructions are three-byte instructions that can access data with variable addresses at any location in memory. The CPU adds the unsigned contents of H:X to the 16-bit unsigned word formed by the two bytes following the opcode. The sum is the effective address of the operand. The first byte after the opcode is the most significant byte of the 16-bit offset; the second byte is the least significant byte of the 16-bit offset; the second byte is the least significant byte of the 16-bit offset; most assemblers determine the shortest form of indexed addressing.

Indexed, 16-bit offset instructions are useful in selecting the k-th element in an n-element table. The table can begin anywhere and can extend as far as the address map allows. The k value would typically be in H:X, and the address of the beginning of the table would be in the bytes following the opcode.

### 9.3.6.6 SP-Relative, 8-Bit Offset (SP1)

Stack pointer, 8-bit offset instructions are three-byte instructions that address operands in much the same way as indexed 8-bit offset instructions, except that the 8-bit offset is added to the value of the stack pointer instead of the index register.

The stack pointer, 8-bit offset addressing mode permits easy addressing of data on the stack. The CPU adds the unsigned byte in the 16-bit stack pointer (SP) register to the unsigned byte following the opcode. The sum is the effective address of the operand. If interrupts are disabled, this addressing mode allows the stack pointer to be used as a second "index" register.

#### Addressing Modes

Stack pointer relative instructions require a pre-byte for access. Consequently, all SP relative instructions take one cycle longer than their index relative counterparts.

### 9.3.6.7 SP-Relative, 16-Bit Offset (SP2)

Stack pointer, 16-bit offset instructions are four-byte instructions used to access data relative to the stack pointer with variable addresses at any location in memory. The CPU adds the unsigned contents of the 16-bit stack pointer to the 16-bit unsigned word formed by the two bytes following the opcode. The sum is the effective address of the operand.

As with direct and extended addressing, most assemblers determine the shortest form of stack pointer addressing. Due to the pre-byte, stack pointer relative instructions take one cycle longer than their index relative counterparts.

Stack pointer, 16-bit offset instructions are useful in selecting the k-th element a an nelement table. The table can begin anywhere and can extend anywhere in memory. The k value would typically be in the stack pointer register, and the address of the beginning of the table is located in the two bytes following the two-byte opcode.

### 9.3.7 Memory to memory Addressing Mode

Memory to memory addressing mode has the following four variations.

### 9.3.7.1 Direct to Direct

This addressing mode is used to move data within the direct page of memory. Both the source operand and the destination operand are in the direct page. The source data is addressed by the first byte immediately following the opcode, and the destination location is addressed by the second byte following the opcode.

### 9.3.7.2 Immediate to Direct

This addressing mode is used to move an 8-bit constant to any location in the direct page memory. The source data is the byte immediately following the opcode, and the destination is addressed by the second byte following the opcode.

### 9.3.7.3 Indexed to Direct, Post Increment

Used only by the MOV instruction, this addressing mode accesses a source operand addressed by the H:X register, and a destination location within the direct page addressed by the byte following the opcode. H:X is incremented after the source operand is accessed.

### 9.3.7.4 Direct to Indexed, Post-Increment

Used only with the MOV instruction, this addressing mode accesses a source operand addressed by the byte following the opcode, and a destination location addressed by the H:X register. H:X is incremented after the destination operand is written.

# 9.4 Operation modes

The CPU can be placed into the following operation modes: stop, wait, background and security.

# 9.4.1 Stop mode

Usually, all system clocks, including the crystal oscillator (when used), are halted during stop mode to minimize power consumption. In such systems, external circuitry is needed to control the time spent in stop mode and to issue a signal to wake up the target MCU when it is time to resume processing. Unlike the earlier M68HC05 and M68HC08 MCUs, the HCS08 V6 can be configured to keep a minimum set of clocks running in stop mode. This optionally allows an internal periodic signal to wake the target MCU from stop mode.

When a host debug system is connected to the background debug pin (BKGD) and the ENBDM control bit has been set by a serial command through the background interface (or because the MCU was reset into active background mode), the oscillator is forced to remain active when the MCU enters stop mode. In this case, if a serial BACKGROUND command is issued to the MCU through the background debug interface while the CPU is in stop mode, CPU clocks will resume and the CPU will enter active background mode where other serial background commands can be processed. This ensures that a host development system can still gain access to a target MCU even if it is in stop mode.

# 9.4.2 Wait mode

The WAIT instruction enables interrupts by clearing the I bit in the CCR. It then halts the clocks to the CPU to reduce overall power consumption while the CPU is waiting for the interrupt or reset event that will wake the CPU from wait mode. When an interrupt or reset event occurs, the CPU clocks will resume and the interrupt or reset event will be processed normally.

If a serial BACKGROUND command is issued to the MCU through the background debug interface while the CPU is in wait mode, CPU clocks will resume and the CPU will enter active background mode where other serial background commands can be processed. This ensures that a host development system can still gain access to a target MCU even if it is in wait mode.

While in wait mode, there are some restrictions on which background debug commands can be used. Only the BACKGROUND command and memory-access-with-status commands are available while in wait mode. The memory-access-with-status commands do not allow memory access, but they report an error indicating that the CPU is in either stop or wait mode. The BACKGROUND command can be used to wake the CPU from wait mode and enter active background mode.

# 9.4.3 Background mode

Background instruction (BGND) is not used in normal user programs because it forces the CPU to stop processing user instructions and enter the active background mode waiting for serial background commands. The only way to resume execution of the user program is through reset or by a host debug system issuing a GO, TRACE1, or TAGGO serial command through the background debug interface.

Software-based breakpoints can be set by replacing an opcode at the desired breakpoint address with the BGND opcode. When the program reaches this breakpoint address, the CPU is forced to active background mode rather than continuing the user program.

The active background mode functions are managed through the background debug controller (BDC) in the HCS08 V6 core. The BDC provides the means for analyzing MCU operation during software development. Active background mode is entered in any of the following ways:

- When the BKGD pin is low at the time the MCU exits reset.
- When a BACKGROUND command is received through the BKGD pin.

- When a BGND instruction is executed.
- When encountering a BDC breakpoint.

Background commands are of two types:

- Non-intrusive commands, defined as commands that can be issued while the user program is running. Non-intrusive commands can be issued through the BKGD pin while the MCU is in run mode; non-intrusive commands can also be executed when the MCU is in the active background mode. Non-intrusive commands include:
  - Memory access commands
  - Memory-access-with-status commands
  - BDC register access commands
  - The BACKGROUND command
- Active background commands, which can be executed only while the MCU is in active background mode. Active background commands include commands to:
  - Read or write CPU registers
  - Trace one user program instruction at a time
  - Leave active background mode to return to the user's application program (GO)

The active background mode is used to program a bootloader or user application program into the flash program memory before the MCU is operated in run mode for the first time. The active background mode can also be used to erase and reprogram the flash memory after it has been previously programmed.

### 9.4.4 Security mode

Usually HCS08 V6 MCUs are implemented with a secure operating mode. When in secure mode, external access to internal memory is restricted, so that only instructions fetched from secure memory can access secure memory.

The method by which the MCU is put into secure mode is not defined by the HCS08 V6 Core. The core receives an external input signal that, when asserted, informs to the core that the MCU is in secure mode.

While in secure mode, the core controls the following set of conditions:

#### **Operation modes**

- 1. The RAM, flash, and EEPROM arrays are considered secure memory. All registers in Direct Page or High Page are considered non-secure memory.
- 2. Read data is tagged as either secure or non-secure during a program read, depending on whether the read is from secure or non-secure memory.
- 3. A data read of secure memory returns a value of \$00 when the current instruction is tagged as non-secure or the access is a BDC access.
- 4. A data write to secure memory is blocked and data at the target address does not change state when the current instruction is tagged as non-secure or the access is through BDC.
- 5. A data write to secure memory is never blocked during the stacking cycles of interrupt service routines.
- 6. Data accesses to either secure or non-secure memory are allowed when the current instruction is tagged as secure.
- 7. BDC accesses to non-secure memory are allowed.

When the device is in the non-secure mode, secure memory is treated the same as nonsecure memory, and all accesses are allowed.

Table 9-2 details the security conditions for allowing or disabling a read access.

		Inputs conc	litions		Read control
Security enabled	Ram, flash or EEPROM access	Program or vector read	Current CPU instruction from secure memory	Current access is via BDC	Read access allowed
0	x	х	Х	x	1
1	0	х	х	x	1
1	1	1	x	x	1
1	1	0	1	0	1
1	1	0	1	1	0
1	1	0	0	0	0
1	1	0	0	1	0

Table 9-2. Security conditions for read access

## 9.5 HCS08 V6 Opcodes

The HCS08 V6 Core has 254 one-byte opcodes and 47 two-byte opcodes, totaling 301 opcodes. For a more detailed description of the HCS08 V6 instructions please refer to the Instruction Set Summary section.

## 9.6 Special Operations

The CPU performs a few special operations that are similar to instructions but do not have opcodes like other CPU instructions. This section provides additional information about these operations.

### 9.6.1 Reset Sequence

Reset can be caused by a power-on-reset (POR) event, internal conditions such as the COP (computer operating properly) watchdog, or by assertion of an external active-low reset pin. When a reset event occurs, the CPU immediately stops whatever it is doing (the MCU does not wait for an instruction boundary before responding to a reset event).

The reset event is considered concluded when the sequence to determine whether the reset came from an internal source is done and when the reset pin is no longer asserted. At the conclusion of a reset event, the CPU performs a 6-cycle sequence to fetch the reset vector from \$FFFE and \$FFFF and to fill the instruction queue in preparation for execution of the first program instruction.

### 9.6.2 Interrupt Sequence

When an interrupt is requested, the CPU completes the current instruction before responding to the interrupt. At this point, the program counter is pointing at the start of the next instruction, which is where the CPU should return after servicing the interrupt. The CPU responds to an interrupt by performing the same sequence of operations as for a software interrupt (SWI) instruction, except the address used for the vector fetch is determined by the highest priority interrupt that is pending when the interrupt sequence started.

The CPU sequence for an interrupt is:

#### Instruction Set Summary

- 1. Store the contents of PCL, PCH, X, A, and CCR on the stack, in that order.
- 2. Set the I bit in the CCR.
- 3. Fetch the high-order half of the interrupt vector.
- 4. Fetch the low-order half of the interrupt vector.
- 5. Delay for one free bus cycle.

Fetch three bytes of program information starting at the address indicated by the interrupt vector to fill the instruction queue in preparation for execution of the first instruction in the interrupt service routine.

After the CCR contents are pushed onto the stack, the I bit in the CCR is set to prevent other interrupts while in the interrupt service routine. Although it is possible to clear the I bit with an instruction in the interrupt service routine, this would allow nesting of interrupts (which is not recommended because it leads to programs that are difficult to debug and maintain).

For compatibility with the earlier M68HC05 MCUs, the high-order half of the H:X index register pair (H) is not saved on the stack as part of the interrupt sequence. The user must use a PSHH instruction at the beginning of the service routine to save H and then use a PULH instruction just before the RTI that ends the interrupt service routine. It is not necessary to save H if you are certain that the interrupt service routine does not use any instructions or auto-increment addressing modes that might change the value of H.

The software interrupt (SWI) instruction is like a hardware interrupt except that it is not masked by the global I bit in the CCR and it is associated with an instruction opcode within the program so it is not asynchronous to program execution.

### Table 9-3. Instruction Set Summary (continued)

# Chapter 10 Flash Memory Module (FTMRH)

## 10.1 Introduction

The FTMRH module implements the following:

• Program flash (flash) memory

The flash memory is ideal for single-supply applications allowing for field reprogramming without requiring external high voltage sources for program or erase operations. The flash module includes a memory controller that executes commands to modify flash memory contents. The user interface to the memory controller consists of the indexed Flash Common Command Object (FCCOB) register which is written to with the command, global address, data, and any required command parameters. The memory controller must complete the execution of a command before the FCCOB register can be written to with a new command.

### CAUTION

A flash byte or longword must be in the erased state before being programmed. Cumulative programming of bits within a flash byte or longword is not allowed.

The flash memory is read as longwords. Read access time is one bus cycle for longwords. For flash memory, an erased bit reads 1 and a programmed bit reads 0.

# 10.2 Feature

### 10.2.1 Flash memory features

The flash memory has the following features:

- 16 KB of flash memory composed of one 16 KB flash block divided into 32 sectors of 512 bytes
- Automated program and erase algorithm with verify

MC9S08PL16S Reference Manual, Rev. 3, 06/2020

- Fast sector erase and longword program operation
- Flexible protection scheme to prevent accidental programming or erasing of flash memory

# 10.2.2 Other flash module features

The flash memory module has the following other features:

- No external high-voltage power supply required for flash memory program and erase operations
- Interrupt generation on flash command completion and flash error detection
- Security mechanism to prevent unauthorized access to the flash memory

# 10.3 Functional description

# 10.3.1 Modes of operation

The flash memory module provides the normal user mode of operation. The operating mode is determined by module-level inputs and affects the FPROT, FCNFG, and FCLKDIV registers.

### 10.3.1.1 Wait mode

The flash memory module is not affected if the MCU enters Wait mode. The flash module can recover the MCU from Wait via the CCIF interrupt. See Flash interrupts.

# 10.3.1.2 Stop mode

If a flash command is active, that is, FSTAT[CCIF] = 0, when the MCU requests Stop mode, the current NVM operation will be completed before the MCU is allowed to enter Stop mode.

# 10.3.2 Flash block read access

If a flash block is read during execution of a command (while FSTAT[CCIF] = 0), the read operation will return invalid data and it will trigger a illegal access exception in the MCU.

## 10.3.3 Flash memory map

The MCU places the flash memory as shown in the following table.

	Table 10-1.	Flash memor	y addressing
--	-------------	-------------	--------------

Global address	Flash size	Description
0x0000_C000-0x0000_FFFF	16 KB	Flash block contains flash configuration field.

## 10.3.4 Flash initialization after system reset

On each system reset, the flash module executes an initialization sequence that establishes initial values for the flash block configuration parameters, the FPROT protection register, and the FOPT and FSEC registers. The initialization routine reverts to built-in default values that leave the module in a fully protected and secured state if errors are encountered during execution of the reset sequence. If an error is detected during the reset sequence, both FSTAT[MGSTAT] bits will be set.

FSTAT[CCIF] is cleared throughout the initialization sequence. The NVM module holds off all CPU access for a portion of the initialization sequence. Flash reads are allowed after the hold is removed. Completion of the initialization sequence is marked by setting FSTAT[CCIF] high, which enables user commands. While FSTAT[CCIF] remains cleared, it is not possible to write on registers FCCOBIX or FCCOB.

If a reset occurs while any flash command is in progress, that command will be immediately aborted. The state of the word being programmed or the sector/block being erased is not guaranteed.

## 10.3.5 Flash command operations

Flash command operations are used to modify flash memory contents.

The command operations contain three steps:

- 1. Configure the clock for flash program and erase command operations.
- 2. Use command write sequence to set flash command parameters and launch execution.
- 3. Execute valid flash commands according to MCU functional mode and MCU security state.

MC9S08PL16S Reference Manual, Rev. 3, 06/2020

#### **Functional description**

The figure below shows a general flowchart of the flash command write sequence.

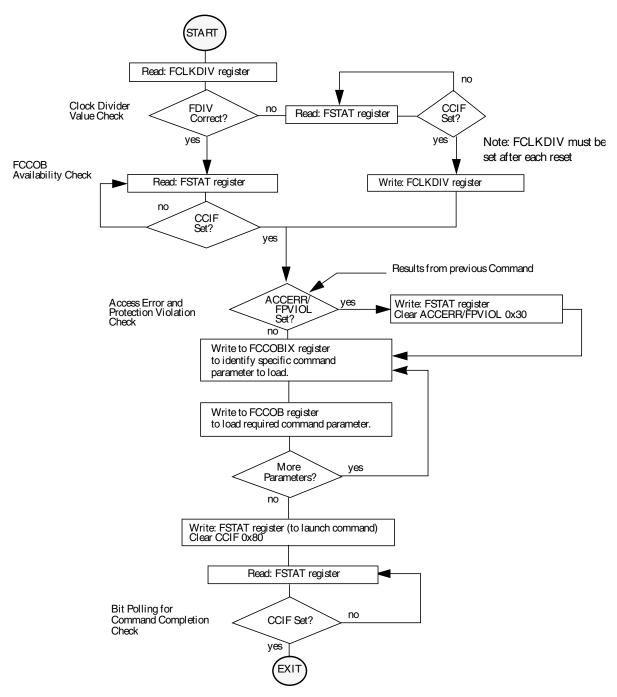

Figure 10-1. Generic flash command write sequence flowchart

### 10.3.5.1 Writing the FCLKDIV register

Prior to issuing any flash program or erase command after a reset, the user is required to write the FCLKDIV register to divide BUSCLK down to a target FCLK of 1 MHz. The following table shows recommended values for FCLKDIV[FDIV] based on BUSCLK frequency.

BUSCLK	frequency	
(M	Hz)	FDIV[5:0]
MIN <sup>1</sup>	MAX <sup>2</sup>	
1.0	1.6	0x00
1.6	2.6	0x01
2.6	3.6	0x02
3.6	4.6	0x03
4.6	5.6	0x04
5.6	6.6	0x05
6.6	7.6	0x06
7.6	8.6	0x07
8.6	9.6	0x08
9.6	10.6	0x09
10.6	11.6	0x0A
11.6	12.6	0x0B
12.6	13.6	0x0C
13.6	14.6	0x0D
14.6	15.6	0x0E
15.6	16.6	0x0F
16.6	17.6	0x10
17.6	18.6	0x11
18.6	19.6	0x12
19.6	20.6	0x13
20.6	21.6	0x14
21.6	22.6	0x15
22.6	23.6	0x16
23.6	24.6	0x17
24.6	25.6	0x18

Table 10-2. FDIV values for various BUSCLK frequencies

1. BUSCLK is greater than this value.

2. BUSCLK is less than or equal to this value.

### CAUTION

Programming or erasing the flash memory cannot be performed if the bus clock runs at less than 0.8 MHz. Setting FCLKDIV[FDIV] too high can destroy the flash memory due to overstress. Setting FCLKDIV[FDIV] too low can result in incomplete programming or erasure of the flash memory cells.

When the FCLKDIV register is written, FCLKDIV[FDIVLD] is set automatically. If FCLKDIV[FDIVLD] is 0, the FCLKDIV register has not been written since the last reset. If the FCLKDIV register has not been written, any flash program or erase command loaded during a command write sequence will not execute and FSTAT[ACCERR] will be set.

## 10.3.5.2 Command write sequence

The memory controller will launch all valid flash commands entered using a command write sequence.

Before launching a command, FSTAT[ACCERR] and FSTAT[FPVIOL] must be cleared and the FSTAT[CCIF] flag will be tested to determine the status of the current command write sequence. If FSTAT[CCIF] is 0, indicating that the previous command write sequence is still active, a new command write sequence cannot be started and all writes to the FCCOB register are ignored.

The FCCOB parameter fields must be loaded with all required parameters for the flash command being executed. Access to the FCCOB parameter fields is controlled via FCCOBIX[CCOBIX].

Flash command mode uses the indexed FCCOB register to provide a command code and its relevant parameters to the memory controller. First, the user must set up all required FCCOB fields. Then they can initiate the command's execution by writing a 1 to FSTAT[CCIF]. This action clears the CCIF command completion flag to 0. When the user clears FSTAT[CCIF], all FCCOB parameter fields are locked and cannot be changed by the user until the command completes (evidenced by the memory controller returning FSTAT[CCIF] to1). Some commands return information to the FCCOB register array.

The generic format for the FCCOB parameter fields in flash command mode is shown in the following table. The return values are available for reading after the FSTAT[CCIF] flag has been returned to 1 by the memory controller. Writes to the unimplemented parameter fields, FCCOBIX[CCOBIX] =110b and FCCOBIX[CCOBIX] = 111b, are ignored with read from these fields returning 0x0000.

Chapter 10 Flash Memory Module (FTMRH)

Table 10-3 shows the generic flash command format. The high byte of the first word in the CCOB array contains the command code, followed by the parameters for this specific flash command. For details on the FCCOB settings required by each command, see the flash command descriptions in Flash command summary .

CCOBIX[2:0]	Byte	FCCOB parameter fields in flash command mode
000	HI	FCMD[7:0] defining flash command
000	LO	Global address [23:16]
001	HI	Global address [15:8]
001	LO	Global address [7:0]
010	HI	Data 0 [15:8]
010	LO	Data 0 [7:0]
011	HI	Data 1 [15:8]
	LO	Data 1 [7:0]
100	HI	Data 2 [15:8]
100	LO	Data 2 [7:0]
101	HI	Data 3 [15:8]
	LO	Data 3 [7:0]

Table 10-3. FCCOB – flash command mode typical usage

The contents of the FCCOB parameter fields are transferred to the memory controller when the user clears the FSTAT[CCIF] command completion flag by writing 1. The CCIF flag will remain clear until the flash command has completed. Upon completion, the memory controller will return FSTAT[CCIF] to 1 and the FCCOB register will be used to communicate any results.

The following table presents the valid flash commands, as enabled by the combination of the functional MCU mode with the MCU security state of unsecured or secured.

MCU secured state is selected by FSEC[SEC].

 Table 10-4.
 Flash commands by mode and security state

FOMD	Command	Unsecured	Secured
FCMD	Command	U <sup>1</sup>	U <sup>2</sup>
0x01	Erase verify all blocks	*	*
0x02	Erase verify block	*	*
0x03	Erase verify flash section	*	*
0x04	Read once	*	*
0x06	Program flash	*	*
0x07	Program once	*	*
0x08	Erase all block	*	*
0x09	Erase flash block	*	*

Table continues on the next page...

FCMD	Command	Unsecured	Secured
	Command	U <sup>1</sup>	U <sup>2</sup>
0x0A	Erase flash sector	*	*
0x0B	Unsecure flash	*	*
0x0C	Verify backdoor access key	*	*
0x0D	Set user margin level	*	*
0x0E	Set factory margin level	*	*

 Table 10-4.
 Flash commands by mode and security state (continued)

1. Unsecured User mode

2. Secured User mode

# 10.3.6 Flash interrupts

The flash module can generate an interrupt when a flash command operation has completed.

Table 10-5.	Flash interrupt source
-------------	------------------------

Interrupt source	Interrupt flag	Local enable	Global (CCR) mask
Electrony complete	CCIF	CCIE	l Bit
Flash command complete	(FSTAT register)	(FCNFG register)	I DIL

## **10.3.6.1** Description of flash interrupt operation

The flash module uses the FSTAT[CCIF] flag in combination with the FCNFG[CCIE] interrupt enable bit to generate the flash command interrupt request.

The logic used for generating the flash module interrupts is shown in the following figure.

Figure 10-2. Flash module interrupts implementation

# 10.3.7 Protection

The FPROT register can be set to protect regions in the flash memory from accidental programing or erasing. Two separate memory regions, one growing downward from global address 0x0\_FFFF in the flash memory, called the higher region, and the remaining addresses in the flash memory, can be activated for protection. The flash memory addresses covered by these protectable regions are shown in the flash memory map.

Default protection settings as well as security information that allows the MCU to restrict access to the flash module are stored in the flash configuration field as described in the table below.

Global address	Size (Bytes)	Description	
0xFF70-0xFF77	8	Backdoor comparison key. See Verify backdoor access key command and Unsecuring the MCU using backdoor key access.	
0xFF78–0xFF7B	4	Reserved	
1	4	Reserved	
0xFF7C <sup>1</sup>	1	Flash protection byte	
0xFF7D <sup>1</sup>	1	Reserved	
0xFF7E <sup>1</sup>	1	Flash nonvolatile byte	
0xFF7F <sup>1</sup>	1	Flash security byte	

Table 10-6. Flash configuration field

1. 0x0\_FF78-0x0\_FF7F form a Flash phrase and must be programmed in a single command write sequence. Each byte in the 0x0\_FF78 - 0x0\_FF7B reserved field should be programmed to 0xFF.

The flash module provides protection to the MCU. During the reset sequence, the FPROT register is loaded with the contents of the flash protection byte in the flash configuration field at global address FF7C in flash memory. The protection functions depend on the configuration of bit settings in FPROT register.

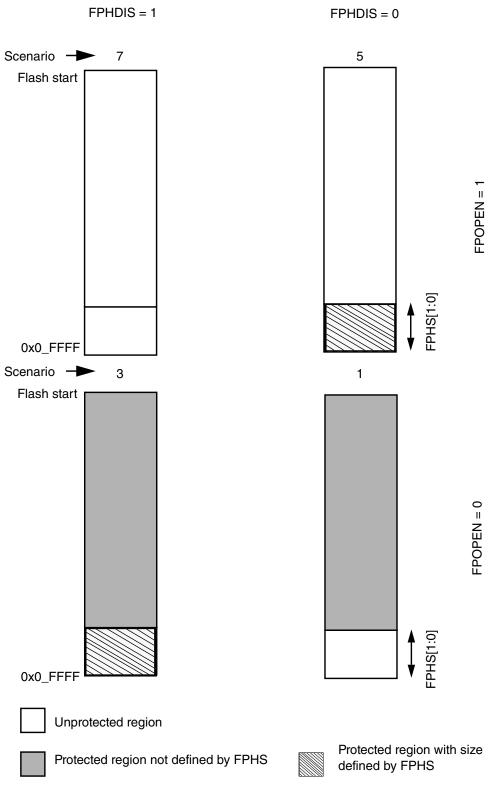

FPOPEN	FPHDIS	Function <sup>1</sup>
1	1	No flash protection
1	0	Protected high range
0	1	Full flash memory protected
0	0	Unprotected high range

Table 10-7. Flash protection function

1. For range sizes, see Table 4.

The flash protection scheme can be used by applications requiring reprogramming in single chip mode while providing as much protection as possible if reprogramming is not required.

All possible flash protection scenarios are shown in the following figure. Although the protection scheme is loaded from the flash memory at global address 0xFF7C during the reset sequence, it can be changed by the user.

#### Figure 10-3. Flash protection scenarios

The general guideline is that flash protection can only be added and not removed. The following table specifies all valid transitions between flash protection scenarios. Any attempt to write an invalid scenario to the FPROT register will be ignored. The contents of the FPROT register reflect the active protection scenario. See the FPROT[FPHS] field descriptions for additional restrictions.

From protection scenario		To protection scenario <sup>1</sup>			
	1	3	5	7	
1	×	×			
3		×			
5		×	×		
7	×	×	×	×	

Table 10-8. Flash protection scenario transitions

1. Allowed transitions marked with X.

The flash protection address range is listed in the following two tables regarding the scenarios in the table above.

FPHS[1:0]	Global address range	Protected size
00	0xF800-0xFFFF	2 KB
01	0xF000–0xFFFF	4 KB
10	0xE000–0xFFFF	8 KB
11	0xC000–0xFFFF	16 KB

Table 10-9. Flash protection higher address range

# 10.3.8 Security

The flash module provides security information to the MCU. The flash security state is defined by FSEC[SEC]. During reset, the flash module initializes the FSEC register using data read from the security byte of the flash configuration field. The security state out of reset can be permanently changed by programming the security byte, assuming that the MCU is starting from a mode where the necessary flash erase and program commands are available and that the upper region of the flash is unprotected. If the flash security byte is successfully programmed, its new value will take effect after the next MCU reset.

The following subsections describe these security-related subjects:

• Unsecuring the MCU using backdoor key access

- Unsecuring the MCU using BDM
- Mode and security effects on flash command availability

## 10.3.8.1 Unsecuring the MCU using backdoor key access

The MCU may be unsecured by using the backdoor key access feature which requires knowledge of the contents of the backdoor keys, which are four 16-bit words programmed at addresses 0xFF70–0xFF77. If the KEYEN[1:0] bits are in the enabled state, the verify backdoor access key command – see Verify backdoor access key command, allows the user to present four prospective keys for comparison to the keys stored in the flash memory via the memory controller. If the keys presented in the verify backdoor access key command match the backdoor keys stored in the flash memory, FSEC[SEC] will be changed to unsecure the MCU. Key values of 0x0000 and 0xFFFF are not permitted as backdoor keys. While the Verify Backdoor Access Key command is active, flash memory will not be available for read access and will return invalid data.

The user code stored in the flash memory must have a method of receiving the backdoor keys from an external stimulus. This external stimulus would typically be through one of the on-chip serial ports.

If the KEYEN[1:0] bits are in the enabled state, the MCU can be unsecured by the backdoor key access sequence described below:

- 1. Follow the command sequence for the verify backdoor access key command as explained in Verify backdoor access key command.
- 2. If the verify backdoor access key command is successful, the MCU is unsecured and FSEC[SEC] is forced to the unsecure state of 10.

The verify backdoor access key command is monitored by the memory controller and an illegal key will prohibit future use of the verify backdoor access key command. A reset of the MCU is the only method to re-enable the verify backdoor access key command. The security as defined in the flash security byte is not changed by using the verify backdoor access key command sequence. The backdoor keys stored in addresses 0xFF70–0xFF77 are unaffected by the verify backdoor access key command sequence. The verify backdoor access key command sequence. The verify backdoor access key command sequence has no effect on the program and erase protections defined in the flash protection register, FPROT.

After the backdoor keys have been correctly matched, the MCU will be unsecured. After the MCU is unsecured, the sector containing the flash security byte can be erased and the flash security byte can be reprogrammed to the unsecure state, if desired. In the unsecure state, the user has full control of the contents of the backdoor keys by programming addresses 0xFF70–0xFF77 in the flash configuration field.

# 10.3.8.2 Unsecuring the MCU using BDM

A secured MCU can be unsecured by using the following method to erase the flash memory:

- 1. Reset the MCU.
- 2. Set FCDIV register as described in Writing the FCLKDIV register
- 3. Configure FPROT register to disable protection in the flash memory.
- 4. Execute the Erase All Blocks command write sequence to erase the flash memory. Alternatively the Unsecure Flash command can be executed.

If the flash memory is verified as erased, the MCU will be unsecured. All BDM commands will now be enabled and the flash security byte may be programmed to the unsecure state by continuing with the following steps:

- 5. Execute the Program Flash command write sequence to program the flash security byte to the unsecured state
- 6. Reset the MCU

# 10.3.8.3 Mode and security effects on flash command availability

The availability of flash module commands depends on the MCU operating mode and security state as shown in Table 10-4.

# 10.3.9 Flash commands

# 10.3.9.1 Flash commands

The following table summarizes the valid flash commands as well as the effects of the commands on the flash block and other resources within the flash module.

## NOTE

All commands in the following table, regardless of MCU mode or security state, cannot be launched while the flash array is being read (i.e. the commands must not be executed if the core is fetching code from the flash). If the core attempts to read the flash while any command is running that may result in an illegal access. Refer to Flash block read access for details.

FCMD	Command	Function on flash memory
0x01	Erase Verify All Blocks	Verifies that all flash blocks are erased
0x02	Erase Verify Block	Verifies that a flash block is erased
0x03	Erase Verify Flash Section	Verifies that a given number of words starting at the address provided are erased
0x04	Read Once	Reads a dedicated 64-byte field in the nonvolatile information register in flash block that was previously programmed using the program once command
0x06	Program Flash	Programs up to two longwords in a flash block
0x07	Program Once	Programs a dedicated 64 byte field in the nonvolatile information register in flash block that is allowed to be programmed only once
0x08	Erase All Block	Erases all flash blocks An erase of all flash blocks is possible only when the FPROT[FPHDIS] and FPROT[FPOEN] and the bit are set prior to launching the command
0x09	Erase Flash Block	Erases a flash block An erase of the full flash block is possible only when FPROT[FPHDIS] and FPROT[FPOEN] are set prior to launching the command.
0x0A	Erase Flash Sector	Erases all bytes in a flash sector
0x0B	Unsecure Flash	Supports a method of releasing MCU security by erasing all flash blocks and verifying that all flash blocks are erased
0x0C	Verify Backdoor Access key	Supports a method of releasing MCU security by verifying a set of security keys
0x0D	Set User Margin Level	Specifies a user margin read level for all flash blocks
0x0E	Set Factory Margin Level	Specifies a factory margin read level for all flash blocks

#### Table 10-10. Flash commands

# 10.3.10 Flash command summary

This section provides details of all available flash commands launched by a command write sequence. The FSTAT[ACCERR] will be set during the command write sequence if any of the following illegal steps are performed, causing the command not to be processed by the memory controller:

- Starting any command write sequence that programs or erases flash memory before initializing the FLCKDIV register.
- Writing an invalid command as part of the command write sequence.
- For additional possible errors, refer to the error handling table provided for each command.

Chapter 10 Flash Memory Module (FTMRH)

If a flash block is read during the execution of an algorithm (FSTAT[CCIF] = 0) on that same block, the read operation will return invalid data.

If FSTAT[ACCERR] or FSTAT[FPVIOL] are set, the user must clear these fields before starting any command write sequence.

#### CAUTION

An flash longword must be in the erased state before being programmed. Cumulative programming of bits within an flash longword is not allowed.

## 10.3.10.1 Erase Verify All Blocks command

The Erase Verify All Blocks command will verify that all flash blocks have been erased.

 Table 10-11.
 Erase Verify All Blocks command FCCOB requirements

CCOBIX[2:0]	FCCOBHI parameters	FCCOBLO parameters
000	0x01	Not required

Upon clearing FSTAT[CCIF] to launch the Erase Verify All Blocks command, the memory controller will verify that the entire flash memory space is erased. The FSTAT[CCIF] flag will set after the erase verify all blocks operation has completed. If all blocks are not erased, it means blank check failed and both FSTAT[MGSTAT] bits will be set.

Table 10-12. Erase verify all blocks command error handling

Register	Error bit	Error condition
	ACCERR	Set if CCOBIX[2:0] != 000 at command launch
	FPVIOL	None
FSTAT	MGSTAT1	Set if any errors have been encountered during the read <sup>1</sup> or if blank check failed
	MGSTAT0	Set if any errors have been encountered during the read or if blank check failed

1. As found in the memory map for NVM

# 10.3.10.2 Erase Verify Block command

The Erase Verify Block command allows the user to verify that an entire flash block has been erased. The FCCOB global address [23:0] bits determine which block must be verified.

Table 10-13.	Erase Verify Block Command FCCOB requirements
--------------	---

CCOBIX[2:0]	FCCOBHI parameters	FCCOBLO parameters
000	0x02	Global address [23:16] to identify flash block
001	Global addr	ess [15:0] in flash block to be verified

Upon clearing FSTAT[CCIF] to launch the erase verify block command, the memory controller will verify that the selected flash block is erased. The FSTAT[CCIF] flag will set after the erase verify block operation has completed. If the block is not erased, it means blank check failed and both FSTAT[MGSTAT] bits will be set.

Table 10-14. Erase Verify Block command error handling

Register	Error bit	Error condition
	ACCERR	Set if CCOBIX[2:0] != 001 at command launch
		Set if an invalid global address [23:0] is supplied <sup>1</sup>
	FPVIOL	None
FSTAT	MGSTAT1	Set if any errors have been encountered during the read or if blank check failed
	MGSTAT0	Set if any errors have been encountered during the read or if blank check failed

1. As found in the memory map for NVM

# 10.3.10.3 Erase Verify Flash Section command

The Erase Verify Flash Section command will verify that a section of code in the flash memory is erased. The Erase Verify Flash Section command defines the starting point of the code to be verified and the number of longwords.

 Table 10-15.
 Erase verify flash section command FCCOB requirements

CCOBIX[2:0]	FCCOBHI parameters	FCCOBLO parameters
000	0x03	Global address [23:16] of flash block
001	Global address [15:0] of the first longwords to be verified	
010	Numl	per of long words to be verified

Upon clearing FSTAT[CCIF] to launch the erase verify flash section command, the memory controller will verify that the selected section of flash memory is erased. The FSTAT[CCIF] flag will set after the erase verify flash section operation has completed. If the section is not erased, it means blank check failed and both FSTAT[MGSTAT] bits will be set.

Register	Error bit	Error condition
		Set if CCOBIX[2:0] != 010 at command launch
		Set if command not available in current mode (see Table 10-4)
	ACCERR	Set if an invalid global address [23:0] is supplied (see Table 10-1) <sup>1</sup>
		Set if a misaligned long words address is supplied (global address[1:0] != 00)
FSTAT		Set if the requested section crosses flash address boundary
	FPVIOL	None
	MGSTAT1	Set if any errors have been encountered during the read <sup>2</sup> or if blank check failed
	MGSTAT0	Set if any errors have been encountered during the read <sup>2</sup> or if blank check failed

Table 10-16. Erase Verify Flash Section command error handling

1. As defined by the memory map for NVM

2. As found in the memory map for NVM

## 10.3.10.4 Read once command

The read once command provides read access to a reserved 64-byte field (8 phrase) located in the nonvolatile information register of flash. The read once field can only be programmed once and can not be erased. It can be used to store the product ID or any other information that can be written only once. It is programmed using the program once command described in Program Once command. To avoid code runaway, the read once command must not be executed from the flash block containing the program once reserved field.

CCOBIX[2:0]	FCCOB parameters	
000	0x04 Not required	
001	Read one	ce phrase index (0x0000 – 0x0007)
010		Read once word 0 value
011		Read once word 1 value
100		Read once word 2 value
101		Read once word 3 value

Table 10-17. Read Once command FCCOB requirements

Upon clearing FSTAT[CCIF] to launch the read once command, a read once phrase is fetched and stored in the FCCOB indexed register. The FSTAT[CCIF] flag will set after the read once operation has completed. Valid phrase index values for the read once command range from 0x0000 to 0x0007. During execution of the read once command, any attempt to read addresses within flash block will return invalid data.

Register	Error bit	Error condition
	ACCERR	Set if CCOBIX[2:0] != 001 at command launch
		Set if command is not available in current mode (see Table 10-4)
FSTAT		Set if an invalid phrase index is supplied
FSTAT		None
	MGSTAT1	Set if any errors have been encountered during the read
	MGSTAT0	Set if any errors have been encountered during the read

 Table 10-18.
 Read Once command error handling

## 10.3.10.5 Program Flash command

The program flash operation will program up to two previously erased longwords in the flash memory using an embedded algorithm.

#### Note

A flash longword must be in the erased state before being programmed. Cumulative programming of bits within a flash longword is not allowed.

 Table 10-19.
 Program Flash command FCCOB requirements

CCOBIX[2:0]	FCCOBHI parameters	FCCOBLO parameters
000	0x06	Global address [23:16] to identify flash block
001	Global address [15	:0] of longwords location to be programmed <sup>1</sup>
010	Word	l 0 (longword 0) program value
011	Word	1 (longword 0) program value
100	Word	I 2 (longword 1) program value
101	Word	I 3 (longword 1) program value

1. Global address [1:0] must be 00.

Upon clearing FSTAT[CCIF] to launch the Program Flash command, the memory controller will program the data longwords to the supplied global address and will then proceed to verify the data longwords read back as expected. The FSTAT[CCIF] flag will set after the program flash operation has completed.

 Table 10-20.
 Program Flash command error handling

Register	Error bit	Error condition
		Set if CCOBIX[2:0] $\neq$ 011 or 101 at command launch
FSTAT	ACCERR	Set if command not available in current mode (see Table 10-4)
		Set if an invalid global address [23:0] is supplied (see Table 10-1.1

Table continues on the next page...

Register	Error bit	Error condition
		Set if a misaligned longword address is supplied (global address [1:0] != 00)
		Set if the requested group of words breaches the end of the flash block.
	FPVIOL	Set if the global address [23:0] points to a protected data
	MGSTAT1	Set if any errors have been encountered during the verify operation
	MGSTAT0	Set if any errors have been encountered during the verify operation

Table 10-20. Program Flash command error handling (continued)

1. As defined by the memory map of NVM.

### 10.3.10.6 Program Once command

The Program Once command restricts programming to a reserved 64-byte field (8 phrases) in the nonvolatile information register located in flash. The program once reserved field can be read using the read once command as described in Read once command. The program once command must be issued only once because the nonvolatile information register in flash cannot be erased. To avoid code runaway, the program once command must not be executed from the flash block containing the program once reserved field.

CCOBIX[2:0]	FCCOB parameters	
000	0x07	Not required
001	Program C	nce phrase index (0x000 – 0x0007)
010	P	rogram once Word 0 value
011	F	Program once Word 1value
100	Р	rogram once Word 2 value
101	P	rogram once Word 3 value

Table 10-21. Program Once command FCCOB requirements

Upon clearing FSTAT[CCIF] to launch the program once command, the memory controller first verifies that the selected phrase is erased. If erased, then the selected phrase will be programmed and then verified with read back. The FSTAT[CCIF] flag will remain clear, setting only after the program once operation has completed.

The reserved nonvolatile information register accessed by the Program Once command cannot be erased, and any attempt to program one of these phrases a second time will not be allowed. Valid phrase index values for the program once command range from 0x0000 to 0x0007. During execution of the program once command, any attempt to read addresses within flash will return invalid data.

Register	Error bit	Error condition
	ACCERR	Set if CCOBIX[2:0] != 101 at command launch
		Set if command not available in current mode (see Table 10-4)
FSTAT		Set if an invalid phrase index is supplied
		Set if the requested phrase has already been programmed <sup>1</sup>
	FPVIOL	None
	MGSTAT1	Set if any errors have been encountered during the verify operation
	MGSTAT0	Set if any errors have been encountered during the verify operation

 Table 10-22.
 Program Once ommand error handling

# 10.3.10.7 Erase All Blocks command

The Erase All Blocks operation will erase the entire flash memory space.

#### Table 10-23. Erase All Blocks command FCCOB requirements

CCOBIX[2:0]	FCCOBHI parameters	FCCOBLO parameters
000	0x08	Not required

Upon clearing FSTAT[CCIF] to launch the Erase All Blocks command, the memory controller will erase the entire NVM memory space and verify that it is erased. If the memory controller verifies that the entire NVM memory space was properly erased, security will be released. Therefore, the device is in unsecured state. During the execution of this command (FSTAT[CCIF] = 0) the user must not write to any NVM module register. The FSTAT[CCIF] flag will set after the erase all blocks operation has completed.

Table 10-24.	Erase All Blocks co	ommand error handling
--------------	---------------------	-----------------------

Register	Error bit	Error condition
	ACCERR	Set if CCOBIX[2:0] ≠ 000 at command launch
	ACCENN	Set if command not available in current mode (see Table 10-4)
FSTAT	FPVIOL	Set if any area of the flash memory is protected
	MGSTAT1	Set if any errors have been encountered during the verify operation <sup>1</sup>
MGSTAT0		Set if any errors have been encountered during the verify operation <sup>1</sup>

1. As found in the memory map for NVM.

# 10.3.10.8 Erase flash block command

The erase flash block operation will erase all addresses in a flash block.

Table 10-25.	Erase flash block command FCCOB requirements
--------------	--

CCOBIX[2:0]	FCCOB parameters	
000	0x09	Global address [23:16] to identify flash block
001	Global address[15:0] in flash block to be erased	

Upon clearing FSTAT[CCIF] to launch the erase flash block command, the memory controller will erase the selected flash block and verify that it is erased. The FSTAT[CCIF] flag will set after the erase flash block operation has completed.

 Table 10-26.
 Erase flash block command error handling

Register	Error Bit	Error Condition
		Set if CCOBIX[2:0] != 001 at command launch
	ACCERR	Set if command not available in current mode (see Table 10-4)
FSTAT		Set if an invalid global address [23:0] is supplied <sup>1</sup>
FSTAT	FPVIOL	Set if an area of the selected flash block is protected
	MGSTAT1	Set if any errors have been encountered during the verify operation <sup>2</sup>
	MGSTAT0	Set if any errors have been encountered during the verify operation <sup>2</sup>

1. As defined by the memory map for NVM.

2. As found in the memory map for NVM.

## 10.3.10.9 Erase flash sector command

The erase flash sector operation will erase all addresses in a flash sector.

CCOBIX[2:0]	FCCOB parameters	
000	0x0A	Global address [23:16] to identify flash block to be erased
001	Global address [15:0] anywhere within the sector to be erased. Refer to Overview for the flash sector size	

Upon clearing FSTAT[CCIF] to launch the erase flash sector command, the memory controller will erase the selected flash sector and then verify that it is erased. The FSTAT[CCIF] flag will be set after the erase flash sector operation has completed.

Register	Error bit	Error condition
	ACCERR	Set if CCOBIX[2:0] != 001 at command launch
		Set if command not available in current mode (see Table 10-4)
		Set if an invalid global address [23:0] is supplied. <sup>1</sup> (see Table 10-1)
FSTAT		Set if a misaligned longword address is supplied (global address [1:0] != 00)
	FPVIOL	Set if the selected flash sector is protected
	MGSTAT1	Set if any errors have been encountered during the verify operation
	MGSTAT0	Set if any errors have been encountered during the verify operation

 Table 10-28.
 Erase flash sector command error handling

1. As defined by the memory map for NVM

## 10.3.10.10 Unsecure flash command

The unsecure flash command will erase the entire flash memory space, and if the erase is successful, will release security.

Table 10-29. Unsecure flash command FCCOB requirements

CCOBIX[2:0]	FCCOB parameters	
000	0x0B Not required	

Upon clearing FSTAT[CCIF] to launch the unsecure flash command, the memory controller will erase the entire flash memory space and verify that it is erased. If the memory controller verifies that the entire flash memory space was properly erased, security will be released. If the erase verify is not successful, the unsecure flash operation sets FSTAT[MGSTAT1] and terminates without changing the security state. During the execution of this command (FSTAT[CCIF] = 0), the user must not write to any flash module register. The FSTAT[CCIF] flag is set after the unsecure flash operation has completed.

Table 10-30. Unsecure flash command error handling

Register	Error bit	Error condition
	ACCERR	Set if CCOBIX[2:0] != 000 at command launch
FSTAT		Set if command is not available in current mode (see Table 10-4)
-	FPVIOL	Set if any area of the flash memory is protected
	MGSTAT1	Set if any errors have been encountered during the verify operation <sup>1</sup>
	MGSTAT0	Set if any errors have been encountered during the verify operation <sup>1</sup>

1. As found in the memory map for NVM

# 10.3.10.11 Verify backdoor access key command

The verify backdoor access key command will execute only if it is enabled by the FSEC[KEYEN] bits. The verify backdoor access key command releases security if usersupplied keys match those stored in the flash security bytes of the flash configuration field. See Table 10-1 for details. The code that performs verifying backdoor access command must be running from RAM.

CCOBIX[2:0]	FCCOBHI parameters	FCCOBLO parameters
000	0x0C	Not required
001	Key 0	
010	Key 1	
011	Key 2	
100	Кеу 3	

Table 10-31. Verify backdoor access key command FCCOB requirements

Upon clearing FSTAT[CCIF] to launch the verify backdoor access key command, the memory controller will check the FSEC[KEYEN] bits to verify that this command is enabled. If not enabled, the memory controller sets the FSTAT[ACCERR] bit. If the command is enabled, the memory controller compares the key provided in FCCOB to the backdoor comparison key in the flash configuration field with Key 0 compared to 0x0400, and so on. If the backdoor keys match, security will be released. If the backdoor keys do not match, security is not released and all future attempts to execute the verify backdoor access key command are aborted (set FSTAT[ACCERR]) until a reset occurs. The FSTAT[CCIF] flag is set after the verify backdoor access key operation has completed.

Table 10-32. Verify backdoor access key command error handling

Register	Error bit	Error condition		
	ACCERR	Set if CCOBIX[2:0] ≠ 100 at command launch		
		Set if an incorrect backdoor key is supplied		
		Set if backdoor key access has not been enabled (KEYEN[1:0] ≠ 10		
FSTAT		Set if the backdoor key has mismatched since the last reset		
	FPVIOL	None		
	MGSTAT1	None		
	MGSTAT0	None		

#### Functional description

## 10.3.10.12 Set user margin level command

The user margin is a small delta to the normal read reference level and, in effect, is a minimum safety margin. That is, if the reads pass at the tighter tolerances of the user margins, the normal reads have at least that much safety margin before users experience data loss.

The set user margin level command causes the memory controller to set the margin level for future read operations of the flash block.

CCOBIX[2:0]	FCCOBHI parameters	FCCOBLO parameters	
000	0x0D	Global address [23:16] to identify flash block	
001	Global address [15:0] to identify flash block		
010	Margin level setting		

Table 10-33. Set user margin level command FCCOB requirements

Upon clearing FSTAT[CCIF] to launch the set user margin level command, the memory controller will set the user margin level for the targeted block and then set the FSTAT[CCIF] flag.

#### Note

Valid margin level settings for the set user margin level command are defined in the following tables.

ССОВ	Level description	
(CCOBIX = 010)		
0x0000	Return to normal level	
0x0001	User margin-1 level <sup>1</sup>	
0x0002	User margin-0 level <sup>2</sup>	

1. Read margin to the erased state

2. Read margin to the programmed state

#### Table 10-35. Set user margin level command error handling

Register	Error bit	Error condition		
	ACCERR	Set if CCOBIX[2:0] != 010 at command launch		
		Set if command is not available in current mode (see Table 10-4)		
		Set if an invalid global address [23:0] is supplied		
FSTAT		Set if an invalid margin level setting is supplied		
	FPVIOL	None		
	MGSTAT1	None		
	MGSTAT0	None		

#### Note

User margin levels can be used to check that NVM memory contents have adequate margin for normal level read operations. If unexpected results are encountered when checking NVM memory contents at user margin levels, a potential loss of information has been detected.

# 10.3.10.13 Set factory margin level command

The set factory margin Level command causes the memory controller to set the margin level specified for future read operations of the flash block.

Table 10-36. Set factory margin level command FCCOB requirements

CCOBIX[2:0]	FCCOBHI parameters FCCOBLO parameters		
000	0x0E	Global address [23:16] to identify flash block	
001	Global address [15:0] to identify flash block		
010	Margin level setting		

Upon clearing FSTAT[CCIF] to launch the set factory margin level command, the memory controller will set the factory margin level for the targeted block and then set the FSTAT[CCIF] flag.

#### Note

Valid margin level settings for the set factory margin level command are defined in the following tables.

Table 10-37. Valid set factory margin level settings

ССОВ		
(CCOBIX = 010)	Level description	
0x0000	Return to normal level	
0x0001	User margin-1 level <sup>1</sup>	
0x0002	User margin-0 level <sup>2</sup>	
0x0003	Factory margin-1 level <sup>1</sup>	
0x0004	Factory margin-0 level <sup>2</sup>	

1. Read margin to the erased state

2. Read margin to the programmed state

Register	Error bit	Error condition
		Set if CCOBIX[2:0] != 010 at command launch
	ACCERR	Set if command is not available in current mode (see Table 10-4)
		Set if an invalid global address [23:0] is supplied
FSTAT		Set if an invalid margin level setting is supplied
	FPVIOL	None
	MGSTAT1	None
	MGSTAT0	None

 Table 10-38.
 Set factory margin level command error handling

### CAUTION

Factory margin levels must only be used during verify of the initial factory programming.

#### Note

Factory margin levels can be used to check that Flash memory contents have adequate margin for data retention at the normal level setting. If unexpected results are encountered when checking flash memory contents at factory margin levels, the fash memory contents must be erased and reprogrammed.

# **10.4** Memory map and register definition

This section presents a high-level summary of the registers and how they are mapped. The registers can be accessed in 32-bits, 16-bits (aligned on data[31:16] or on data[15:0]) or 8-bits. In the case of the writable registers, the write accesses are forbidden during flash command execution. For more details, see Caution note in Flash memory map.

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
3020	Flash Clock Divider Register (FTMRH_FCLKDIV)	8	R/W	00h	10.4.1/165
3021	Flash Security Register (FTMRH_FSEC)	8	R	Undefined	10.4.2/166
3022	Flash CCOB Index Register (FTMRH_FCCOBIX)	8	R/W	00h	10.4.3/167
3024	Flash Configuration Register (FTMRH_FCNFG)	8	R/W	00h	10.4.4/167
3026	Flash Status Register (FTMRH_FSTAT)	8	R/W	80h	10.4.5/168
3028	Flash Protection Register (FTMRH_FPROT)	8	R/W	See section	10.4.6/169
302A	Flash Common Command Object Register:High (FTMRH_FCCOBHI)	8	R/W	00h	10.4.7/170

#### **FTMRH** memory map

Table continues on the next page...

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
302B	Flash Common Command Object Register: Low (FTMRH_FCCOBLO)	8	R/W	00h	10.4.8/171
302C	Flash Option Register (FTMRH_FOPT)	8	R/W	Undefined	10.4.9/171

#### FTMRH memory map (continued)

# 10.4.1 Flash Clock Divider Register (FTMRH\_FCLKDIV)

The FCLKDIV register is used to control timed events in program and erase algorithms.

All bits in the FCLKDIV register are readable, bit 7 is not writable, bit 6 is write-oncehigh and controls the writability of the FDIV field in user mode. In BDM mode, bits 6-0 are writable any number of times but bit 7 remains unwritable.

## NOTE

The FCLKDIV register must not be written while a flash command is executing (FSTAT[CCIF] = 0)

Address: 3020h base + 0h offset = 3020h Bit 7 6 5 4 3 2 1 0 FDIVLD Read FDIVLCK FDIV Write Reset 0 0 0 0 0 0 0 0

#### FTMRH\_FCLKDIV field descriptions

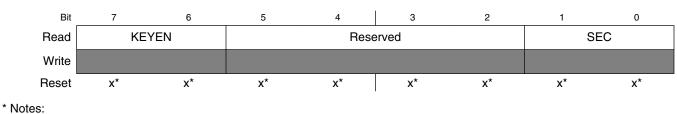

Field	Description
7 FDIVLD	Clock Divider Loaded
	0 FCLKDIV register has not been written since the last reset.
	1 FCLKDIV register has been written since the last reset.
6 FDIVLCK	Clock Divider Locked
	0 FDIV field is open for writing.
	1 FDIV value is locked and cannot be changed. After the lock bit is set high, only reset can clear this bit and restore writability to the FDIV field in user mode.
FDIV	Clock Divider Bits
	FDIV[5:0] must be set to effectively divide BUSCLK down to 1MHz to control timed events during flash program and erase algorithms. Refer to the table in the Writing the FCLKDIV register for the recommended values of FDIV based on the BUSCLK frequency.

# 10.4.2 Flash Security Register (FTMRH\_FSEC)

The FSEC register holds all bits associated with the security of the MCU and NVM module. All fields in the FSEC register are readable but not writable. During the reset sequence, the FSEC register is loaded with the contents of the flash security byte in the flash configuration field located in flash memory.

See Security for security function.

Address: 3020h base + 1h offset = 3021h

• x = Undefined at reset.

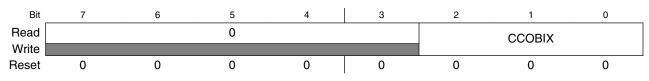

Field	Description
7–6 KEYEN	Backdoor Key Security Enable Bits
	The KEYEN[1:0] bits define the enabling of backdoor key access to the flash module.
	NOTE: 01 is the preferred KEYEN state to disable backdoor key access.
	00 Disabled
	01 Disabled
	10 Enabled
	11 Disabled
5–2 Reserved	This field is reserved.
SEC	Flash Security Bits
	Defines the security state of the MCU. If the flash module is unsecured using backdoor key access, the SEC field is forced to 10.
	<b>NOTE:</b> 01 is the preferred SEC state to set MCU to secured state.
	00 Secured
	01 Secured
	10 Unsecured
	11 Secured

#### FTMRH\_FSEC field descriptions

# 10.4.3 Flash CCOB Index Register (FTMRH\_FCCOBIX)

The FCCOBIX register is used to index the FCCOB register for NVM memory operations.

Address: 3020h base + 2h offset = 3022h

#### FTMRH\_FCCOBIX field descriptions

Field	Description	
-	This field is reserved. This read-only field is reserved and always has the value 0.	
	ommon Command Register Index	
	Selects which word of the FCCOB register array is being read or written to.	

# 10.4.4 Flash Configuration Register (FTMRH\_FCNFG)

The FCNFG register enables the flash command complete interrupt.

Address: 3020h base + 4h offset = 3024h

Bit	7	6	5	4	3	2	1	0
Read	CCIE	0				0		
Write								
Reset	0	0	0	0	0	0	0	0

#### FTMRH\_FCNFG field descriptions

Field	Description
7 CCIE	Command Complete Interrupt Enable
	Controls interrupt generation when a flash command has completed.
	0 Command complete interrupt is disabled.
	1 An interrupt will be requested whenever the CCIF flag in the FSTAT register is set.
6–5	This field is reserved.
Reserved	This read-only field is reserved and always has the value 0.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

# 10.4.5 Flash Status Register (FTMRH\_FSTAT)

The FSTAT register reports the operational status of the flash module.

Address: 3020h base + 6h offset = 3026h

Bit	7	6	5	4	3	2	1	0
Read	CCIF	0	ACCERR	FPVIOL	MGBUSY	0	MGS	STAT
Write	COIF		AUGERR PPVIOL					
Reset	1	0	0	0	0	0	0	0

#### FTMRH\_FSTAT field descriptions

Field	Description
7 CCIF	Command Complete Interrupt Flag
	Indicates that a flash command has completed. The CCIF flag is cleared by writing a 1 to CCIF to launch a command and CCIF will stay low until command completion or command violation.
	0 Flash command is in progress.
	1 Flash command has completed.
6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5	Flash Access Error Flag
ACCERR	Indicates an illegal access has occurred to the flash memory caused by either a violation of the command write sequence or issuing an illegal flash command. While ACCERR is set, the CCIF flag cannot be cleared to launch a command. Writing 1 to this field clears it while writing a 0 to this field has no effect.
	0 No access error is detected.
	1 Access error is detected.
4 FPVIOL	Flash Protection Violation Flag
	Indicates an attempt was made to program or erase an address in a protected area of flash memory during a command write sequence. Writing 1 to FPVIOL clears this field while writing 0 to this field has no effect. While FPIOL is set, it is not possible to launch a command or start a command write sequence.
	0 No protection violation is detected.
	1 Protection violation is detected.
3 MGBUSY	Memory Controller Busy Flag
	Reflects the active state of the memory controller.
	0 Memory controller is idle.
	1 Memory controller is busy executing a flash command (CCIF = 0).
2	This field is reserved.
Reserved	This read-only field is reserved and always has the value 0.
MGSTAT	Memory Controller Command Completion Status Flag

Table continues on the next page ...

Field	Description		
	One or more MGSTAT flag bits are set if an error is detected during execution of a flash command or during the flash reset sequence.		
	<b>NOTE:</b> Reset value can deviate from the value shown if a double bit fault is detected during the reset sequence.		

#### FTMRH\_FSTAT field descriptions (continued)

# 10.4.6 Flash Protection Register (FTMRH\_FPROT)

The FPROT register defines which flash sectors are protected against program and erase operations.

The unreserved bits of the FPROT register are writable with the restriction that the size of the protected region can only be increased (see Protection). All the unreserved bits of the FPROT register are writable without restriction in active Background Debug Mode (BDM).

During the reset sequence, the FPROT register is loaded with the contents of the flash protection byte in the flash configuration field at global address 0x40D located in flash memory. To change the flash protection that will be loaded during the reset sequence, the upper sector of the flash memory must be unprotected, then the flash protection byte must be reprogrammed.

Trying to alter data in any protected area in the flash memory will result in a protection violation error and the FPVIOL bit will be set in the FSTAT register. The block erase of a flash block is not possible if any of the flash sectors contained in the same flash block are protected.

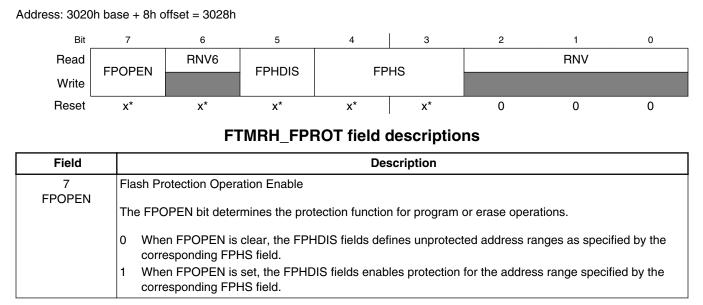

Table continues on the next page...

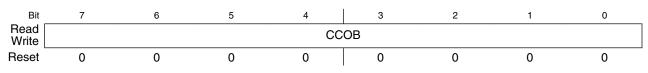

Field	Description
6 RNV6	Reserved Nonvolatile Bit
	The RNV bit must remain in the erased state.
5 FPHDIS	Flash Protection Higher Address Range Disable
	The FPHDIS bit determines whether there is a protected/unprotected area in a specific region of the flash memory ending with global address 0x7FFF.
	0 Protection/Unprotection enabled.
	1 Protection/Unprotection disabled.
4–3 FPHS	Flash Protection Higher Address Size
	The FPHS bits determine the size of the protected/unprotected area in flash memory. The FPHS bits can be written to only while the FPHDIS bit is set.
RNV	Reserved Nonvolatile Bit
	The RNV bit must remain in the erased state.

#### FTMRH\_FPROT field descriptions (continued)

# 10.4.7 Flash Common Command Object Register:High (FTMRH\_FCCOBHI)

The FCCOB is an array of six words addressed via the CCOBIX index found in the FCCOBIX register. Byte-wide reads and writes are allowed to the FCCOB register.

Address: 3020h base + Ah offset = 302Ah

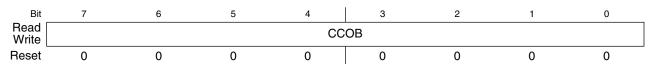

#### FTMRH\_FCCOBHI field descriptions

Field	Description
ССОВ	Common Command Object Bit 15:8
	High 8 bits of Common Command Object register

# 10.4.8 Flash Common Command Object Register: Low (FTMRH\_FCCOBLO)

The FCCOB is an array of six words addressed via the CCOBIX index found in the FCCOBIX register. Byte-wide reads and writes are allowed to the FCCOB register.

Address: 3020h base + Bh offset = 302Bh

#### FTMRH\_FCCOBLO field descriptions

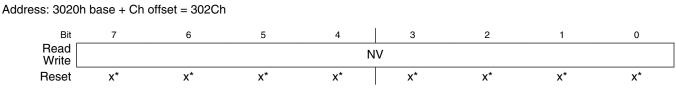

Field	Description
ССОВ	Common Command Object Bit 7:0
	Low 8 bits of Common Command Object register

# 10.4.9 Flash Option Register (FTMRH\_FOPT)

The FOPT register is the flash option register.

In active Background Debug Mode (BDM), all bits in the FOPT register are readable and writable. In other modes, all bits in the FOPT register are readable but not writable.

During the reset sequence, the FOPT register is loaded from the flash nonvolatile byte in the flash configuration field at global address 0x040F located in flash memory as indicated by reset condition.

\* Notes:

• x = Undefined at reset.

Field	Description
	Nonvolatile Bits The NV[7:0] bits are available as nonvolatile bits. During the reset sequence, the FOPT register is loaded from the flash nonvolatile byte in the flash configuration field at global address 0x40F located in flash memory.

#### FTMRH\_FOPT field descriptions

# Chapter 11 Port Control (PORT)

# 11.1 Introduction

This device has three sets of I/O ports, which include up to 18 general-purpose I/O pins.

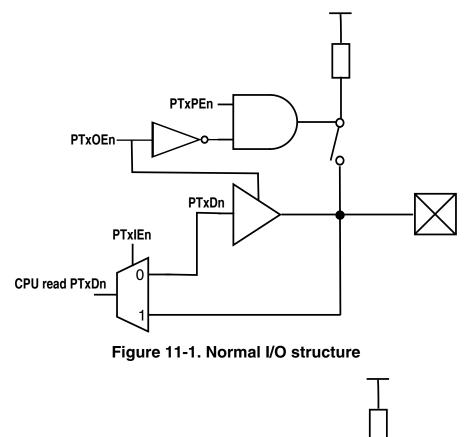

Not all pins are available on all devices. See Table 3-1 to determine which functions are available for a specific device.

Many of the I/O pins are shared with on-chip peripheral functions, as shown in Table 3-1. The peripheral modules have priority over the I/O, so when a peripheral is enabled, the associated I/O functions are disabled.

After reset, the shared peripheral functions are disabled so that the pins are controlled by the parallel I/O except PTA4 and PTA5 that are default to BKGD/MS and RESET function. All of the parallel I/O are configured as high-impedance (Hi-Z). The pin control functions for each pin are configured as follows:

- input disabled (PTxIEn = 0),
- output disabled (PTxOEn = 0), and
- internal pullups disabled (PTxPEn = 0).

The following figures show the structures of each I/O pin.

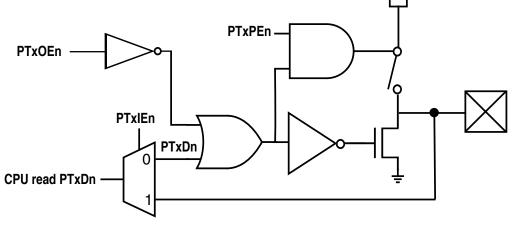

Figure 11-2. I/O structure when I<sup>2</sup>C functions SDA/SCL is enabled

# 11.2 Port data and data direction

Reading and writing of parallel I/O is accomplished through the port data registers (PTxD). The direction, input or output, is controlled through the input enable or output enable registers.

After reset, all parallel I/O default to the Hi-Z state. The corresponding bit in output enable register (PTxOE) or input enable register (PTxIE) must be configured for output or input operation. Each port pin has an input enable bit and an output enable bit. When PTxIEn = 1, a read from PTxDn returns the input value of the associated pin; when PTxIEn = 0, a read from PTxDn returns the last value written to the port data register.

## NOTE

The PTxOE must be clear when the corresponding pin is used as input function to avoid contention. If set the corresponding PTxOE and PTxIE bits at same time, read from PTxDn will always return the output data.

When a peripheral module or system function is in control of a port pin, the data direction register bit still controls what is returned for reads of the port data register, even though the peripheral system has overriding control of the actual pin direction.

When a shared analog function is enabled for a pin, all digital pin functions are disabled. A read of the port data register returns a value of 0 for any bits that have shared analog functions enabled. In general, whenever a pin is shared with both an alternate digital function and an analog function, the analog function has priority such that if both of the digital and analog functions are enabled, the analog function controls the pin.

A write of valid data to a port data register must occur before setting the output enable bit of an associated port pin. This ensures that the pin will not be driven with an incorrect data value.

# 11.3 Internal pullup enable

An internal pullup device can be enabled for each port pin by setting the corresponding bit in one of the pullup enable registers (PTxPEn). The internal pullup device is disabled if the pin is configured as an output by the parallel I/O control logic, or by any shared peripheral function, regardless of the state of the corresponding pullup enable register bit. The internal pullup device is also disabled if the pin is controlled by an analog function.

# 11.4 Input glitch filter setting

A filter is implemented for each port pin that is configured as a digital input. It can be used as a simple low-pass filter to filter any glitch that is introduced from the pins of GPIO, IRQ, RESET, and KBI. The glitch width threshold can be adjusted easily by

#### Pin behavior in stop mode

setting registers PORT\_IOFLTn and PORT\_FCLKDIV between 1~4096 BUSCLKs (or 1~128 LPOCLKs). This configurable glitch filter can take the place of an on board external analog filter, and greatly improve the EMC performance.

Setting register PORT\_IOFLTn can configure the filter of the whole port, etc. set PORT\_IOFLT0[FLTA] will affect all PTAn pins.

# 11.5 Pin behavior in stop mode

In stop3 mode, all I/O is maintained because internal logic circuitry stays powered up. Upon recovery, normal I/O function is available to the user.

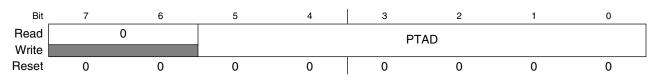

# 11.6 Port data registers

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Port A Data Register (PORT_PTAD)	8	R/W	00h	11.6.1/177

#### **PORT memory map**

# 11.6.1 Port A Data Register (PORT\_PTAD)

Address: 0h base + 0h offset = 0h

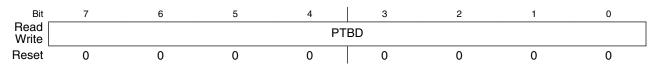

#### **PORT\_PTAD** field descriptions

Field	Description
7–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
PTAD	Port A Data Register Bits
	For port A pins that are configured as inputs, a read returns the logic level on the pin.
	For port A pins that are configured as outputs, a read returns the last value that was written to this register.
	For port A pins that are configured as Hi-Z, a read returns uncertainty data.
	Writes are latched into all bits of this register. For port A pins that are configured as outputs, the logic level is driven out of the corresponding MCU pin.
	Reset forces PTAD to all 0s, but these 0s are not driven out of the corresponding pins because reset also configures all port pins as high-impedance inputs with pullups disabled.

## 11.6.2 Port B Data Register (PORT\_PTBD)

Address: 0h base + 1h offset = 1h

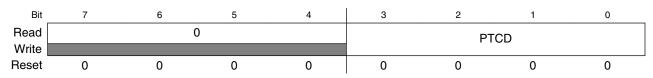

#### **PORT\_PTBD** field descriptions

Field	Description
PTBD	Port B Data Register Bits
	For port B pins that are configured as inputs, a read returns the logic level on the pin.
	For port B pins that are configured as outputs, a read returns the last value that was written to this register.
	For port B pins that are configured as Hi-Z, a read returns uncertainty data.
	Writes are latched into all bits of this register. For port B pins that are configured as outputs, the logic level is driven out of the corresponding MCU pin.
	Reset forces PTBD to all 0s, but these 0s are not driven out of the corresponding pins because reset also configures all port pins as high-impedance inputs with pullups disabled.

# 11.6.3 Port C Data Register (PORT\_PTCD)

Address: 0h base + 2h offset = 2h

#### **PORT\_PTCD** field descriptions

Field	Description
7–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
PTCD	Port C Data Register Bits
	For port C pins that are configured as inputs, a read returns the logic level on the pin.
	For port C pins that are configured as outputs, a read returns the last value that was written to this register.
	For port C pins that are configured as Hi-Z, a read returns uncertainty data.
	Writes are latched into all bits of this register. For port C pins that are configured as outputs, the logic level is driven out of the corresponding MCU pin.
	Reset forces PTCD to all 0s, but these 0s are not driven out of the corresponding pins because reset also configures all port pins as high-impedance inputs with pullups disabled.

# 11.6.4 Port A Output Enable Register (PORT\_PTAOE)

Field	Description
	0 Pullup disabled for port B bit 3.
	1 Pullup enabled for port B bit 3.
2 PTBPE2	Pull Enable for Port B Bit 2
	This control bit determines if the internal pullup device is enabled for the associated PTB pin. For port B pins that are configured as outputs or Hi-Z, these bits have no effect.
	0 Pullup disabled for port B bit 2.
	1 Pullup enabled for port B bit 2.
1 PTBPE1	Pull Enable for Port B Bit 1
	This control bit determines if the internal pullup device is enabled for the associated PTB pin. For port B pins that are configured as outputs or Hi-Z, these bits have no effect.
	0 Pullup disabled for port B bit 1.
	1 Pullup enabled for port B bit 1.
0 PTBPE0	Pull Enable for Port B Bit 0
	This control bit determines if the internal pullup device is enabled for the associated PTB pin. For port B pins that are configured as outputs or Hi-Z, these bits have no effect.
	0 Pullup disabled for port B bit 0.
	1 Pullup enabled for port B bit 0.

### 11.6.15 Port C Pullup Enable Register (PORT\_PTCPE)

Address: 0h base + 30F2h offset = 30F2h

Bit	7	6	5	4	3	2	1	0
Read		0			PTCPE3	PTCPE2	PTCPE1	PTCPE0
Write					1 101 20	1 101 22	110121	1 101 20
Reset	0	0	0	0	0	0	0	0

#### **PORT\_PTCPE** field descriptions

Field	Description
7–4	This field is reserved.
Reserved	This read-only field is reserved and always has the value 0.
3	Pull Enable for Port C Bit 3
PTCPE3	This control bit determines if the internal pullup device is enabled for the associated PTC pin. For port C pins that are configured as outputs or Hi-Z, these bits have no effect.
	<ol> <li>Pullup disabled for port C bit 3.</li> <li>Pullup enabled for port C bit 3.</li> </ol>
2	Pull Enable for Port C Bit 2
PTCPE2	This control bit determines if the internal pullup device is enabled for the associated PTC pin. For port C pins that are configured as outputs or Hi-Z, these bits have no effect.

Table continues on the next page...

Port data registers

Field	Description
	0 Pullup disabled for port C bit 2.
	1 Pullup enabled for port C bit 2.
1 PTCPE1	Pull Enable for Port C Bit 1
	This control bit determines if the internal pullup device is enabled for the associated PTC pin. For port C pins that are configured as outputs or Hi-Z, these bits have no effect.
	0 Pullup disabled for port C bit 1.
	1 Pullup enabled for port C bit 1.
0 PTCPE0	Pull Enable for Port C Bit 0
	This control bit determines if the internal pullup device is enabled for the associated PTC pin. For port C pins that are configured as outputs or Hi-Z, these bits have no effect.
	0 Pullup disabled for port C bit 0.
	1 Pullup enabled for port C bit 0.

# Chapter 12 Keyboard Interrupts (KBI)

## 12.1 Introduction

### 12.1.1 Features

The KBI features include:

- Up to eight keyboard interrupt pins with individual pin enable bits
- Each keyboard interrupt pin is programmable as:
  - falling-edge sensitivity only
  - rising-edge sensitivity only
  - both falling-edge and low-level sensitivity
  - both rising-edge and high-level sensitivity
- One software-enabled keyboard interrupt
- Exit from low-power modes

## 12.1.2 Modes of Operation

This section defines the KBI operation in:

- Wait mode
- Stop mode
- Background debug mode

External signals description

### 12.1.2.1 KBI in Wait mode

Executing the Wait instruction places the MCU into Wait mode. The KBI interrupt should be enabled (KBI\_SC[KBIE] = 1), if desired, before executing the Wait instruction, allowing the KBI to continue to operate while the MCU is in Wait mode. An enabled KBI pin (KBI\_PE[KBIPEn] = 1) can be used to bring the MCU out of Wait mode if the KBI interrupt is enabled (KBI\_SC[KBIE] = 1).

### 12.1.2.2 KBI in Stop modes

Executing the Stop instruction places the MCU into Stop mode (when Stop is selected), where the KBI can operate asynchronously. If this is the desired behavior, the KBI interrupt must be enabled (KBI\_SC[KBIE] = 1) before executing the Stop instruction, allowing the KBI to continue to operate while the MCU is in Stop mode. An enabled KBI pin (KBI\_PE[KBIPEn] = 1) can be used to bring the MCU out of Stop mode if the KBI interrupt is enabled (KBI\_SC[KBIE] = 1).

## 12.1.3 Block Diagram

The block diagram for the keyboard interrupt module is shown below.

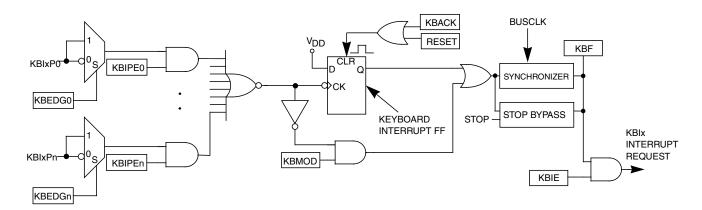

Figure 12-1. KBI block diagram

# 12.2 External signals description

The KBI input pins can be used to detect either falling edges, or both falling edge and low-level interrupt requests. The KBI input pins can also be used to detect either rising edges, or both rising edge and high-level interrupt requests.

The signal properties of KBI are shown in the following table:

	<b>v</b> 1	
Signal	Function	I/O
KBIPn	Keyboard interrupt pins	I

#### Table 12-1. External signals description

## 12.3 Register definition

The KBI includes following registers:

- A pin status and control register, KBI\_SC
- A pin enable register, KBI\_PE
- An edge select register, KBI\_ES

See the direct-page register summary in the Memory chapter for the absolute address assignments for all KBI registers. This section refers to registers and control bits only by their names.

Some MCUs may have more than one KBI, so register names include placeholder characters to identify which KBI is being referenced.

# 12.4 Memory Map and Registers

### KBI memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
3C	KBI Status and Control Register (KBI0_SC)	8	R/W	00h	12.4.1/194
307C	KBI Pin Enable Register (KBI0_PE)	8	R/W	00h	12.4.2/195
307D	KBI Edge Select Register (KBI0_ES)	8	R/W	00h	12.4.3/195

## 12.4.1 KBI Status and Control Register (KBIx\_SC)

#### KBI\_SC contains the status flag and control bits, which are used to configure the KBI.

Address: 3Ch base + 0h offset = 3Ch

Bit	7	6	5	4	3	2	1	0
Read		0			KBF		KBIE	KBMOD
Write						KBACK	NDIL	REMOD
Reset	0	0	0	0	0	0	0	0

KBIx\_SC field descriptions

Description						
This field is reserved. This read-only field is reserved and always has the value 0.						
KBI Interrupt Flag KBF indicates when a KBI interrupt request is detected. Writes have no effect on KBF.						
<ul><li>KBI interrupt request not detected.</li><li>KBI interrupt request detected.</li></ul>						
KBI Acknowledge Writing a 1 to KBACK is part of the flag clearing mechanism.						
<ul> <li>KBI Interrupt Enable</li> <li>KBIE determines whether a KBI interrupt is enabled or not.</li> <li>0 KBI interrupt not enabled.</li> <li>1 KBI interrupt enabled.</li> </ul>						
<ul> <li>KBI Detection Mode</li> <li>KBMOD (along with the KBEDG bits) controls the detection mode of the KBI interrupt pins.</li> <li>0 Keyboard detects edges only.</li> <li>1 Keyboard detects both edges and levels.</li> </ul>						

## 12.4.2 KBI Pin Enable Register (KBIx\_PE)

KBI\_PE contains the pin enable control bits.

Address: 3Ch base + 3040h offset = 307Ch

#### KBIx\_PE field descriptions

Field	Description					
KBIPE	(BI Pin Enables					
	Each of the KBIPEn bits enable the corresponding KBI interrupt pin.					
	0 Pin is not enabled as KBI interrupt.					
	1 Pin is enabled as KBI interrupt.					

### 12.4.3 KBI Edge Select Register (KBIx\_ES)

#### KBI\_ES contains the edge select control bits.

Address: 3Ch base + 3041h offset = 307Dh

Bit	7	6	5	4	3	2	1	0
Read Write	KBEDG							
Reset	0	0	0	0	0	0	0	0

#### KBIx\_ES field descriptions

Field	Description
KBEDG	KBI Edge Selects
	Each of the KBEDGn bits selects the falling edge/low-level or rising edge/high-level function of the corresponding pin.
	0 Falling edge/low level.
	1 Rising edge/high level.

# **12.5 Functional Description**

This on-chip peripheral module is called a keyboard interrupt module because originally it was designed to simplify the connection and use of row-column matrices of keyboard switches. However, these inputs are also useful as extra external interrupt inputs and as an external means of waking the MCU from stop or wait low-power modes.

The KBI module allows up to eight pins to act as additional interrupt sources. Writing to the KBI\_PE[KBIPEn] bits independently enables or disables each KBI pin. Each KBI pin can be configured as edge sensitive or edge and level sensitive based on the KBI\_SC[KBMOD] bit. Edge sensitive can be software programmed to be either falling or rising; the level can be either low or high. The polarity of the edge or edge and level sensitivity is selected using the KBI\_ES[KBEDGn] bits.

# 12.5.1 Edge-only sensitivity

Synchronous logic is used to detect edges. A falling edge is detected when an enabled keyboard interrupt (KBI\_PE[KBIPEn]=1) input signal is seen as a logic 1 (the deasserted level) during one bus cycle and then a logic 0 (the asserted level) during the next cycle. A rising edge is detected when the input signal is seen as a logic 0 (the deasserted level) during one bus cycle and then a logic 1 (the asserted level) during the next cycle.

Before the first edge is detected, all enabled keyboard interrupt input signals must be at the deasserted logic levels. After any edge is detected, all enabled keyboard interrupt input signals must return to the deasserted level before any new edge can be detected.

A valid edge on an enabled KBI pin will set KBI\_SC[KBF]. If KBI\_SC[KBIE] is set, an interrupt request will be presented to the MPU. Clearing of KBI\_SC[KBF] is accomplished by writing a 1 to KBI\_SC[KBACK].

# 12.5.2 Edge and level sensitivity

A valid edge or level on an enabled KBI pin will set KBI\_SC[KBF]. If KBI\_SC[KBIE] is set, an interrupt request will be presented to the MCU. Clearing of KBI\_SC[KBF] is accomplished by writing a 1 to KBI\_SC[KBACK], provided all enabled keyboard inputs are at their deasserted levels. KBI\_SC[KBF] will remain set if any enabled KBI pin is asserted while attempting to clear KBI\_SC[KBF] by writing a 1 to KBI\_SC[KBACK].

## 12.5.3 KBI Pullup Resistor

Each KBI pin, if enabled by KBI\_PE, can be configured via the associated I/O port pull enable register, see chapter, to use:

- an internal pullup resistor, or
- no resistor

If an internal pullup resistor is enabled for an enabled KBI pin, the associated I/O port pull select register (see I/O Port chapter) can be used to select an internal pullup resistor.

## 12.5.4 KBI initialization

When a keyboard interrupt pin is first enabled, it is possible to get a false keyboard interrupt flag. To prevent a false interrupt request during keyboard initialization, the user should do the following:

- 1. Mask keyboard interrupts by clearing KBI\_SC[KBIE].
- 2. Enable the KBI polarity by setting the appropriate KBI\_ES[KBEDGn] bits.
- 3. Before using internal pullup resistors, configure the associated bits in PORT\_.
- 4. Enable the KBI pins by setting the appropriate KBI\_PE[KBIPEn] bits.
- 5. Write to KBI\_SC[KBACK] to clear any false interrupts.
- 6. Set KBI\_SC[KBIE] to enable interrupts.

# Chapter 13 Internal Clock Source (ICS)

# 13.1 Chip specific ICS information

If ICS is in FEI or FEE mode, the ICS\_C2[BDIV] cannot be set to 000.

# 13.2 Introduction

The internal clock source (ICS) module provides clock source choices for the MCU. The module contains a frequency-locked loop (FLL) as a clock source that is controllable by either an internal or an external reference clock. The module can provide this FLL clock or either of the internal or external reference clocks as a source for the MCU system clock. There are also signals provided to control a low-power oscillator (OSC) module for glitch-free clock modes transitions. These signals configure and enable the OSC module to generate its external crystal/resonator clock (OSC\_OUT) used by peripheral modules and as the ICS external reference clock source. The ICS external reference clock can be the external crystal/resonator (OSC\_OUT) supplied by an OSC, or it can be another external clock source.

The ICS clock source chosen is passed through a reduced bus divider (BDIV) which allows a lower final output clock frequency to be derived.

## 13.2.1 Features

The key features of the ICS module are given below:

- Internal reference clock has 9 trim bits for accuracy
- Internal or external reference clocks can be used to control the FLL.
- Selectable dividers for external reference clock to ensure proper input frequency to FLL.
- Internal or external reference clocks can be selected as the clock source for the MCU.
- FLL Engaged Internal mode is automatically selected out of reset.

- FLL lock detector and external clock monitor
  - FLL lock detector with interrupt capability
  - External reference clock monitor with reset capability
- Digitally controlled oscillator optimized for 32-40 MHz frequency range

## 13.2.2 Block diagram

The following figure is the ICS block diagram.

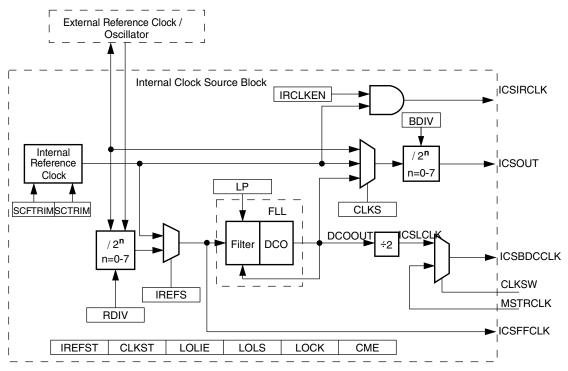

Figure 13-1. Internal clock source (ICS) block diagram

## 13.2.3 Modes of operation

There are seven modes of operation for the ICS: FEI, FEE, FBI, FBILP, FBE, FBELP, and STOP. Each of these modes is explained briefly in the following subsections.

## 13.2.3.1 FLL engaged internal (FEI)

In FLL engaged internal mode, which is the default mode, the ICS supplies a clock derived from the FLL which is controlled by the internal reference clock.

### 13.2.3.2 FLL engaged external (FEE)

In FLL engaged external mode, the ICS supplies a clock derived from the FLL which is controlled by an external reference clock source.

### 13.2.3.3 FLL bypassed internal (FBI)

In FLL bypassed internal mode, the FLL is enabled and controlled by the internal reference clock, but is bypassed. The ICS supplies a clock derived from the internal reference clock.

### 13.2.3.4 FLL bypassed internal low power (FBILP)

In FLL bypassed internal low power mode, the FLL is disabled and bypassed, and the ICS supplies a clock derived from the internal reference clock.

### 13.2.3.5 FLL bypassed external (FBE)

In FLL bypassed external mode, the FLL is enabled and controlled by an external reference clock, but is bypassed. The ICS supplies a clock derived from the external reference clock source.

### 13.2.3.6 FLL bypassed external low power (FBELP)

In FLL bypassed external low power mode, the FLL is disabled and bypassed, and the ICS supplies a clock derived from the external reference clock.

### 13.2.3.7 Stop (STOP)

In Stop mode, the FLL is disabled and the internal or the ICS external reference clocks source (OSC\_OUT) can be selected to be enabled or disabled. The ICS does not provide any MCU clock sources.

#### NOTE

The DCO frequency changes from the pre-stop value to its reset value and the FLL needs to reacquire the lock before the

frequency is stable. Timing sensitive operations must wait for the FLL acquisition time,  $t_{Acquire}$ , before executing.

## 13.3 External signal description

There are no ICS signals that connect off chip.

## 13.4 Register definition

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
3038	ICS Control Register 1 (ICS_C1)	8	R/W	04h	13.4.1/202
3039	ICS Control Register 2 (ICS_C2)	8	R/W	20h	13.4.2/203
303A	ICS Control Register 3 (ICS_C3)	8	R/W	See section	13.4.3/204
303B	ICS Control Register 4 (ICS_C4)	8	R/W	00h	13.4.4/205
303C	ICS Status Register (ICS_S)	8	R/W	10h	13.4.5/205

## 13.4.2 ICS Control Register 2 (ICS\_C2)

Address: 3038h base + 1h offset = 3039h

Bit	7	6	5	4	3	2	1	0
Read		BDIV		LP		0	)	
Write								
Reset	0	0	1	0	0	0	0	0

**Register definition** 

Field	Description				
7–5 BDIV	Bus Frequency Divider				
	Selects the amount to divide down the clock source selected by ICS_C1[CLKS]. This controls the bus frequency.				
	000 Encoding 0—Divides the selected clock by 1.				
	001 Encoding 1—Divides the selected clock by 2 (reset default).				
	010 Encoding 2—Divides the selected clock by 4.				
	011 Encoding 3—Divides the selected clock by 8.				
	100 Encoding 4—Divides the selected clock by 16.				
	101 Encoding 5—Divides the selected clock by 32.				
	110 Encoding 6—Divides the selected clock by 64.				
	111 Encoding 7—Divides the selected clock by 128.				
4 LP	Low Power Select				
	Controls whether the FLL is disabled in FLL bypassed modes.				
	0 FLL is not disabled in bypass mode.				
	1 FLL is disabled in bypass modes unless debug is active.				
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.				

#### ICS\_C2 field descriptions

### 13.4.3 ICS Control Register 3 (ICS\_C3)

Address: 3038h base + 2h offset = 303Ah

Bit	7	6	5	4	3	2	1	0
Read Write				SCT	RIM			
Reset	<b>X</b> *	X*	Х*	<b>x</b> *	X*	X*	Х*	x*

\* Notes:

• SCTRIM is loaded during reset from a factory programmed location when not in BDM mode. If in a BDM mode, SCTRIM gets loaded with a value of 0x80. x = Undefined at reset.

#### ICS\_C3 field descriptions

Field	Description		
SCTRIM	Slow Internal Reference Clock Trim Setting		
	Controls the slow internal reference clock frequency by controlling the internal reference clock period. The bits are binary weighted. In other words, bit 1 adjusts twice as much as bit 0. Increasing the binary value of SCTRIM will increase the period, and decreasing the value will decrease the period. An additional fine trim bit is available as the ICS_C4[SCFTRIM].		
	ICS_C3 is automatically loaded during reset from a factory programmed location when not in a debug mode. The factory programmed trim value adjusts the internal oscillator frequency to fint_ft as specified in the datasheet. The user can provide a custom trim value to attain other internal reference clock frequencies within the fint_t range. The custom trim value must be programmed into reserved flash location and copied to ICS_C3 during code initialization.		

## 13.4.4 ICS Control Register 4 (ICS\_C4)

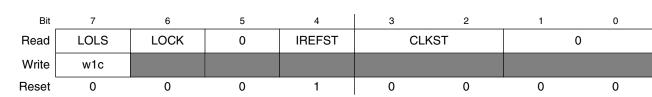

Address: 3038h base + 3h offset = 303Bh

#### **ICS\_C4** field descriptions

Field	Description
7 LOLIE	Loss of Lock Interrupt
	Determines if an interrupt request is made following a loss of lock indication. This field has an effect only when ICS_S[LOLS] is set.
	0 No request on loss of lock.
	1 Generates an interrupt request on loss of lock.
6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 CME	Clock Monitor Enable
	Determines if a reset request is made following a loss of external clock indication. This field must be set to a logic 1 only when the ICS is in an operational mode that uses the external clock (FEE, FBE, or FBELP).
	0 Clock monitor is disabled.
	1 Generates a reset request on loss of external clock.
4–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0	Slow Internal Reference Clock Fine Trim
SCFTRIM	Controls the smallest adjustment of the internal reference clock frequency. Setting SCFTRIM will increase the period and clearing SCFTRIM will decrease the period by the smallest amount possible.
	ICS_C4[SCFTRIM] is automatically loaded during reset from a factory programmed location when not in a debug mode. The factory programmed trim value adjusts the internal oscillator frequency to fint_ft as specified in the datasheet. The user can provide a custom trim value to attain other internal reference clock frequencies within the fint_t range. The custom fine trim bit value must be programmed into reserved flash location and copied to ICS_C4 during code initialization.

## 13.4.5 ICS Status Register (ICS\_S)

Address: 3038h base + 4h offset = 303Ch

Field	Description			
7 LOLS	Loss of Lock Status			
	Indicates the lock status for the FLL. LOLS is set when lock detection is enabled and after acquiring lock, the FLL output frequency has fallen outside the lock exit frequency tolerance, from $\pm 4.7\%$ to $\pm 5.97\%$ . ICS_C4[LOLIE] determines whether an interrupt request is made when set. LOLS is cleared by reset or by writing a logic 1 to LOLS when LOLS is set. Writing a logic 0 to LOLS has no effect.			
	0 FLL has not lost lock since LOLS was last cleared.			
	1 FLL has lost lock since LOLS was last cleared.			
6 LOCK	Lock Status			
	Indicates whether the FLL has acquired lock. Lock detection is disabled when FLL is disabled. If the lock status bit is set then changing the value of any of the following fields IREFS, RDIV[2:0], or, if in FEI or FBI modes, SCTRIM[7:0] will cause the lock status bit to clear and stay cleared until the FLL has reacquired lock. Stop mode entry will also cause the lock status bit to clear and stay cleared until the FLL has reacquired lock.			
	0 FLL is currently unlocked.			
	1 FLL is currently locked.			
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.			
4 IREFST	Internal Reference Status Indicates the current source for the reference clock. This field does not update immediately after a write to			
	ICS_C1[IREFS] due to internal synchronization between clock domains.			
	0 Source of reference clock is external clock.			
	1 Source of reference clock is internal clock.			
3–2 CLKST	Clock Mode Status			
	Indicates the current clock mode. This field doesn't update immediately after a write to ICS_C1[CLKS] due to internal synchronization between clock domains.			
	00 Output of FLL is selected.			
	01 FLL Bypassed, internal reference clock is selected.			
	10 FLL Bypassed, external reference clock is selected.			
	11 Reserved.			
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.			

#### ICS\_S field descriptions

# 13.5 Functional description

## 13.5.1 Operational modes

The seven states of the ICS are shown as a state diagram and are described below. The arrows indicate the allowed movements among the states.

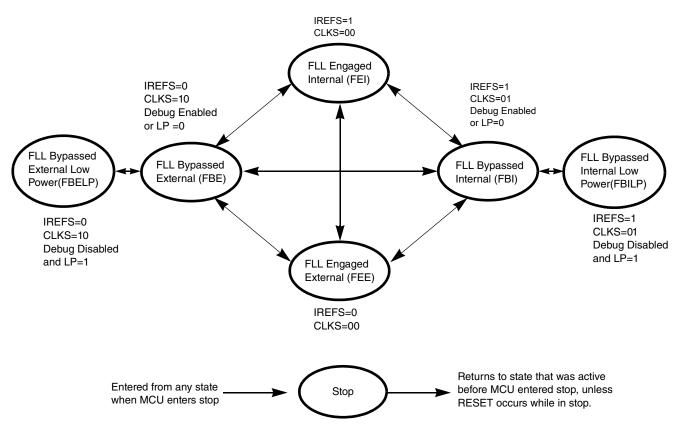

Figure 13-2. Clock switching modes

## 13.5.1.1 FLL engaged internal (FEI)

FLL engaged internal (FEI) is the default mode of operation and is entered when all the following conditions occur:

- 00b is written to ICS\_C1[CLKS].
- 1b is written to ICS\_C1[IREFS].

In FLL engaged internal mode, the ICSOUT clock is derived from the FLL clock, which is controlled by the internal reference clock. The FLL loop locks the frequency to 1024 times the internal reference frequency. The internal reference clock is enabled.

### 13.5.1.2 FLL engaged external (FEE)

The FLL engaged external (FEE) mode is entered when all the following conditions occur:

- 00b is written to ICS\_C1[CLKS].
- 0b is written to ICS\_C1[IREFS].
- ICS\_C1[RDIV] and OSC\_CR[RANGE] are written to divide external reference clock to be within the range of 31.25 kHz to 39.0625 kHz.

#### Functional description

In FLL engaged external mode, the ICSOUT clock is derived from the FLL clock which is controlled by the external reference clock source. The FLL loop locks the frequency to 1024 times the external reference frequency, as selected by ICS\_C1[RDIV] and OSC\_CR[RANGE]. The external reference clock is enabled.

### 13.5.1.3 FLL bypassed internal (FBI)

The FLL bypassed internal (FBI) mode is entered when all the following conditions occur:

- 01b is written to ICS\_C1[CLKS].
- 1b is written to ICS\_C1[IREFS].
- BDM mode is active or ICS\_C2[LP] bit is written to 0.

In FLL bypassed internal mode, the ICSOUT clock is derived from the internal reference clock. The FLL clock is controlled by the internal reference clock, and the FLL loop locks the FLL frequency to 1024 times the internal reference frequency. The internal reference clock is enabled.

### 13.5.1.4 FLL bypassed internal low power (FBILP)

The FLL bypassed internal low power (FBILP) mode is entered when all the following conditions occur:

- 01b is written to ICS\_C1[CLKS].
- 1b is written to ICS\_C1[IREFS].
- BDM mode is not active and ICS\_C2[LP] bit is written to 1b.

In FLL bypassed internal low-power mode, the ICSOUT clock is derived from the internal reference clock and the FLL is disabled. The internal reference clock is enabled.

## 13.5.1.5 FLL bypassed external (FBE)

The FLL bypassed external (FBE) mode is entered when all the following conditions occur:

- 10b is written to ICS\_C1[CLKS].
- Ob is written to ICS\_C1[IREFS].
- ICS\_C1[RDIV] and OSC\_CR[RANGE] fields are written to divide external reference clock to be within the range of 31.25 kHz to 39.0625 kHz.
- BDM mode is active or 0b is written to ICS\_C2[LP].

#### Chapter 13 Internal Clock Source (ICS)

In FLL bypassed external mode, the ICSOUT clock is derived from the external reference clock source. The FLL clock is controlled by the external reference clock, and the FLL loop locks the FLL frequency to 1024 times the external reference frequency, as selected by ICS\_C1[RDIV] and OSC\_CR[RANGE], the external reference clock is enabled.

### 13.5.1.6 FLL bypassed external low power (FBELP)

The FLL bypassed external low-power (FBELP) mode is entered when all the following conditions occur:

- 10b is written to ICS\_C1[CLKS].
- 0b is written to ICS\_C1[IREFS].
- BDM mode is not active and ICS\_C2[LP] bit is written to 1b.

In FLL bypassed external low-power mode, the ICSOUT clock is derived from the external reference clock source and the FLL is disabled. The external reference clock source is enabled.

### 13.5.1.7 Stop

#### NOTE

The DCO frequency changes from the pre-stop value to its reset value and the FLL need to re-acquire the lock before the frequency is stable. Timing sensitive operations must wait for the FLL acquisition time,  $t_{Acquire}$ , before executing.

Stop mode is entered whenever the MCU enters a STOP state. In this mode, all ICS clock signals are static except in the following cases:

ICSIRCLK will be active in Stop mode when all the following conditions occur:

- 1b is written to ICS\_C1[IRCLKEN].
- 1b is written to ICS\_C1[IREFSTEN].

## 13.5.2 Mode switching

ICS\_C1[IREFS] can be changed at anytime, but the actual switch to the newly selected clock is shown by ICS\_S[IREFST]. When switching between FLL engaged internal (FEI) and FLL engaged external (FEE) modes, the FLL begins locking again after the switch is completed.

**Functional description** 

ICS\_C1[CLKS] can also be changed at anytime, but the actual switch to the newly selected clock is shown by ICS\_S[CLKST]. If the newly selected clock is not available, the previous clock remains selected.

#### NOTE

When mode switching is from FEE, FBE or FBELP to FEI, it is suggested to wait IREFST switch completion, then change ICS\_C1[CLKS].

## 13.5.3 Bus frequency divider

ICS\_C2[BDIV] can be changed anytime and the actual switch to the new frequency occurs immediately.

## 13.5.4 Low-power field usage

The Low-Power (LP) field in the ICS\_C2 register is provided to allow the FLL to be disabled and thus conserve power when it is not being used.

However, in some applications it may be desirable to allow the FLL to be enabled and to lock for maximum accuracy before switching to an FLL engaged mode. To do this, write 0b to ICS\_C2[LP].

# 13.5.5 Internal reference clock

When ICS\_C1[IRCLKEN] is set, the internal reference clock signal is presented as ICSIRCLK, which can be used as an additional clock source. To re-target the ICSIRCLK frequency, write a new value to the ICS\_C3[SCTRIM] bits to trim the period of the internal reference clock:

- Writing a larger value slows down the ICSIRCLK frequency.
- Writing a smaller value to the ICS\_C3 register speeds up the ICSIRCLK frequency.

The trim bits affect the ICSOUT frequency if the ICS is in FLL engaged internal (FEI), FLL bypassed internal (FBI), or FLL bypassed internal low power (FBILP) mode.

Until ICSIRCLK is trimmed, programming low bus divider (ICS\_C2[BDIV]) factors may result in ICSOUT frequencies that exceed the maximum chip-level frequency and violate the chip-level clock timing specifications.

If ICS\_C1[IREFSTEN] is set and 1b is written to ICS\_C1[IRCLKEN], the internal reference clock keeps running during Stop mode in order to provide a fast recovery upon exiting Stop mode.

All MCU devices are factory programmed with a trim value in a reserved memory location. This value is uploaded to the ICS\_C3 register and ICS\_C4[SCFTRIM] during any reset initialization. For finer precision, trim the internal oscillator in the application and set ICS\_C4[SCFTRIM] accordingly.

# 13.5.6 Fixed frequency clock

The ICS presents the divided FLL reference clock as ICSFFCLK for use as an additional clock source. ICSFFCLK frequency must be no more than 1/4 of the ICSOUT frequency to be valid. Because of this requirement, in bypass modes, the ICSFFCLK is valid only in bypass external modes (FBE and FBELP) for the following conditions of ICS\_C2[BDIV], and divider factor of ICS\_C1[RDIV] and OSC\_CR[RANGE ] values:

if OSC\_CR[RANGE ] is high,

- ICS\_C2[BDIV] = 000, ICS\_C1[RDIV]  $\ge$  010
- ICS\_C2[BDIV] = 001 (divide by 2), ICS\_C1[RDIV] ≥ 011
- ICS\_C2[BDIV] = 010 (divide by 4), ICS\_C1[RDIV] ≥ 100
- ICS\_C2[BDIV] = 011 (divide by 8), ICS\_C1[RDIV] ≥ 101

# 13.5.7 FLL lock and clock monitor

## 13.5.7.1 FLL clock lock

In FBE and FEE modes, the clock detector source uses the external reference as the reference. When FLL is detected from lock to unlock, ICS\_S[LOLS] is set. An interrupt will be generated if ICS\_C4[LOLIE] is set. ICS\_S[LOLS] is cleared by reset or by writing a logic 1 to ICS\_S[LOLS] when ICS\_S[LOLS] is set. Writing a logic 0 to ICS\_S[LOLS] has no effect.

In FBI and FEI modes, the lock detector source uses the internal reference as the reference. When FLL is detected from lock to unlock, ICS\_S[LOLS] is set. An interrupt will be generated if ICS\_C4[LOLIE] is set. ICS\_S[LOLS] is cleared by reset or by writing a logic 1 to ICS\_S[LOLS] when ICS\_S[LOLS] is set. Writing a logic 0 to ICS\_S[LOLS] has no effect.

```
Functional description
```

In FBELP and FBILP modes, the FLL is not on so that lock detect function is not applicable.

### 13.5.7.2 External reference clock monitor

In FBE, FEE, or FBELP modes, if 1 is written to ICS\_C4[CME], the clock monitor is enabled. If the external reference falls below a certain frequency, the MCU will reset. The will be set to indicate the error.

# Chapter 14 Oscillator (OSC)

## 14.1 Chip specific OSC information

#### NOTE

The OSC\_OUT in this chapter is the OSCOUT from chip specific view.

## 14.2 Introduction

### 14.2.1 Overview

The OSC module provides the clock source for the MCU. The OSC module, in conjunction with an external crystal or resonator, generates a clock for the MCU that can be used as reference clock or bus clock.

## 14.2.2 Features and modes

Key features of the OSC module are:

- Supports 32 kHz crystals (low range mode)
- Supports 4–20 MHz crystals and resonators (high range mode)
- Automatic gain control (AGC) to optimize power consumption in both frequency ranges using low-power mode (low gain mode)
- High gain option in both frequency ranges: 32 kHz, 4–20 MHz
- Voltage and frequency filtering to guarantee clock frequency and stability
- Supports to be enabled by ICS.

## 14.2.3 Block diagram

See the following figure for OSC module block diagram.

The OSC module uses a crystal or resonator to generate three filtered oscillator clock signals(XTL\_CLK). The XTL\_CLK can work in Stop mode since they come from Hard block which always has power.

The OSCOS decides whether OSC\_OUT comes from internal oscillators(XTL\_CLK) or directly from external clock driven on EXTAL pin. The OSCOS signal allows the XTAL pad to be used as I/O or test clock.

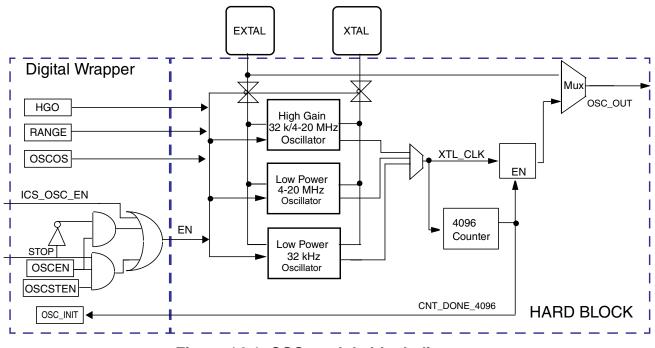

Figure 14-1. OSC module block diagram

# 14.3 Signal description

The following table shows the user-accessible signals available for the OSC module. See the chip-level specification to find out which signals are actually connected to external pins.

Signal	Description	I/O	
EXTAL	External clock/oscillator input	Analog input	
XTAL	Oscillator output	Analog output	

Table 14-1.	OSC signal	descriptions
-------------	------------	--------------

# 14.4 External crystal / resonator connections

The connections for a crystal/resonator frequency reference are shown in Figure 14-2 and Figure 14-3. When using low-frequency, low-power mode, the only external component is the crystal or resonator itself. In the other oscillator modes, load capacitors  $(C_x, C_y)$  and feedback resistor  $(R_F)$  are required. In addition, a series resistor  $(R_S)$  may be used in high-gain modes. Recommended component values are listed in the data sheet.

Oscillator mode	Connections	
Low frequency, high gain	Connection2	
Low frequency, low-power	Connection1	
High frequency, high gain (4–20 MHz)	Connection2	
High frequency, low-power (4–20 MHz)	Connection2	

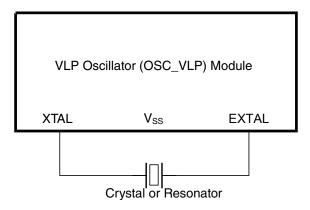

Figure 14-2. Crystal/resonator connections - connection 1

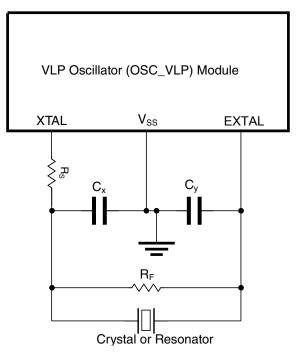

Figure 14-3. Crystal/resonator connections - connection 2

## 14.5 External clock connections

In external clock mode (OSC\_CR[OSCOS] = 0), the pins can be connected as shown in the following figure.

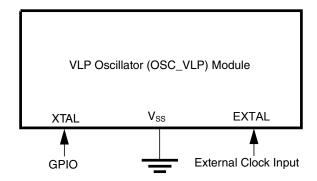

Figure 14-4. External clock connections

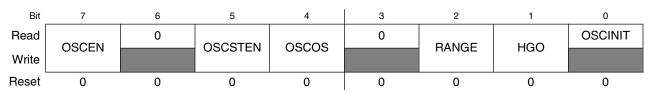

# 14.6 Memory map and register descriptions

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
303E	OSC Control Register (OSC_CR)		R/W	00h	14.6.1/217

#### OSC memory map

### 14.6.1 OSC Control Register (OSC\_CR)

Address: 303Eh base + 0h offset = 303Eh

#### **OSC\_CR** field descriptions

Field	Description
7 OSCEN	OSC Enable
	Enables the OSC module. The OSC module can also be enabled by the ICS module.
	0 OSC module is disabled.
	1 OSC module is enabled.
6	This field is reserved.
Reserved	This read-only field is reserved and always has the value 0.
5 OSCSTEN	OSC Enable in Stop mode
	Controls whether or not the OSC clock remains enabled when MCU enters Stop mode and OSCEN is set. OSCSTEN has no effect if ICS requests OSC enable.
	0 OSC clock is disabled in Stop mode.
	1 OSC clock stays enabled in Stop mode.
4 OSCOS	OSC Output Select
	Selects the output clock of the OSC module.
	0 External clock source from EXTAL pin is selected.
	1 Oscillator clock source is selected.
3	This field is reserved.
Reserved	This read-only field is reserved and always has the value 0.
2 RANGE	Frequency Range Select
HANGE	Selects the frequency range for the OSC module. This bit must be configured before the OSC is enabled and DO NOT change it after the OSC is enabled

Table continues on the next page ...

#### MC9S08PL16S Reference Manual, Rev. 3, 06/2020

Field	Description
	0 Low frequency range of 32 kHz.
	1 High frequency range of 4–20 MHz.
1 HGO	High Gain Oscillator Select
	Controls the OSC mode of operation.
	0 Low-power mode
	1 High-gain mode
0 OSCINIT	OSC Initialization
	This field is set after the initialization cycles of oscillator are completed.
	0 Oscillator initialization is not complete.
	1 Oscillator initialization is completed.

### OSC\_CR field descriptions (continued)

# 14.7 Functional description

### 14.7.1 OSC module states

There are three states of the OSC module. A state diagram is shown in Figure 14-5. The states and the transitions among each other are described in this section.

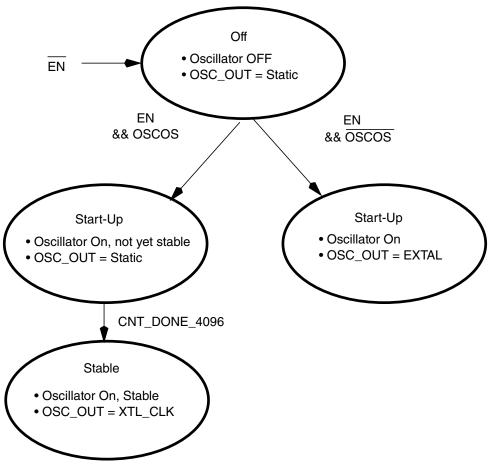

Figure 14-5. OSC module state diagram

EN is decided by OSC\_CR[OSCEN], Stop, OSC\_CR[OSCSTEN], and external request (ICS\_OSC\_EN). See the following table for details.

EN	ICS_OSC_EN	OSC_CR[OSCEN]	OSC_CR[OSCSTEN]	Stop
1	1	-	-	-
1	0	1	-	0
1	0	1	1	1
0	0	1	0	1
0	0	0	-	-

Table 14-3. EN status

Functional description

### 14.7.1.1 Off

The off state is entered whenever the EN signal is negated. Upon entering this state, XTL\_CLK and OSC\_OUT is static. The EXTAL and XTAL pins are also decoupled from all other oscillator circuitry in this state. The OSC module circuitry is configured to draw minimal current.

### 14.7.1.2 Oscillator startup

The oscillator startup state is entered whenever the oscillator is first enabled (EN transitions high) and OSC\_CR[OSCOS] is high. In this state, the OSC module is enabled and oscillations are starting up, but have not yet stabilized. When the oscillation amplitude becomes large enough to pass through the input buffer, XTL\_CLK begins clocking the counter. When the counter has seen 4096 cycles of XTL\_CLK, the oscillator is considered stable and XTL\_CLK is passed to the output clock OSC\_OUT.

### 14.7.1.3 Oscillator stable

The oscillator stable state is entered whenever the oscillator is enabled (EN is high), OSC\_CR[OSCOS] is high, and the counter has seen 4096 cycles of XTL\_CLK (CNT\_DONE\_4096 is high). In this state, the OSC module is producing a stable output clock on OSC\_OUT. Its frequency is determined by the external components being used.

### 14.7.1.4 External clock mode

The external clock state is entered when the oscillator is enabled(EN is high) and OSC\_CR[OSCOS] is low. In this state, the OSC module is set up to buffer (with hysteresis) a clock from EXTAL onto the OSC\_OUT. Its frequency is determined by the external clock being supplied.

# 14.7.2 OSC module modes

The oscillator is a Pierce-type oscillator that supports external crystals or resonators operating over the frequency ranges shown in the following table. These modes assume EN = 1,  $OSC\_CR[OSCOS] = 1$ .

Chapter 14 Oscillator (OSC)

RANGE	HGO	Mode	Frequency range
0	1	Low-frequency, high-gain flo(min) up to flo(m	
0	0	Low-frequency, low-power (VLP)	
1	1	High-frequency mode1, high- gain f <sub>hi</sub> (min) up to f <sub>hi</sub>	
1	0	High-frequency mode1, low- power	

 Table 14-4.
 Oscillator modes

### 14.7.2.1 Low-frequency, high-gain mode

In low-frequency, high-gain mode (OSC\_CR[RANGE] = 0, OSC\_CR[HGO] = 1) the oscillator uses a simple inverter-style amplifier. The gain is set to achieve rail-to-rail oscillation amplitudes. The oscillator input buffer in this mode is single-ended. It provides low pass frequency filtering as well as hysteresis for voltage filtering and converts the output to logic levels.

### 14.7.2.2 Low-frequency, low-power mode

In low-frequency, low-power mode (OSC\_CR[RANGE] = 0, OSC\_CR[HGO] = 0), the oscillator uses a gain control loop to minimize power consumption. As the oscillation amplitude increases, the amplifier current is reduced. This continues until a desired amplitude is achieved at steady-state.

The oscillator input buffer in this mode is single-ended. It provides low pass frequency filtering as well as hysteresis for voltage filtering and converts the output to logic levels.

In this mode, the amplifier inputs, gain-control input, and input buffer input are all capacitively coupled for leakage tolerance (not sensitive to the DC level of EXTAL).

Also in this mode, all external components except for the resonator itself are integrated, which includes the load capacitors and feeback resistor which biases EXTAL.

# 14.7.2.3 High-frequency, high-gain mode

In high-frequency, high-gain Mode (OSC\_CR[RANGE] = 1, OSC\_CR[HGO] = 1), the oscillator uses a simple inverter-style amplifier. The gain is set to achieve rail-to-rail oscillation amplitudes.

#### Functional description

The oscillator input buffer in this mode is single-ended. It provides low pass frequency filtering as well as hysteresis for voltage filtering and converts the output to logic levels.

### 14.7.2.4 High-frequency, low-power mode

In high-frequency, low-power mode (OSC\_CR[RANGE] = 1, OSC\_CR[HGO] = 0) the oscillator uses a gain control loop to minimize power consumption. As the oscillation amplitude increases, the amplifier current is reduced. This continues until a desired amplitude is achieved at steady-state.

The oscillator input buffer in this mode is differential. It provides low pass frequency filtering as well as hysteresis for voltage filtering and converts the output to logic levels.

### 14.7.3 Counter

The oscillator output clock (OSC\_OUT) is gated off until the counter has detected 4096 cycles of its input clock (XTL\_CLK). Once 4096 cycles are complete, the counter passes XTL\_CLK onto OSC\_OUT. This counting timeout is used to guarantee output clock stability.

### 14.7.4 Reference clock pin requirements

The OSC module requires use of both the EXTAL and XTAL pins to generate an output clock in oscillator mode but requires only the EXTAL pin in external clock mode. The EXTAL and XTAL pins can be used for I/O or test clock purposes as long as the specifications listed in the data sheet are met.

# Chapter 15 FlexTimer Module (FTM)

# 15.1 Chip specific FTM information

This device contains up to two FTM modules of one 6-channel FTM2 and one 2-channel FTM0. Each FTM module has independent external clock input. Both FTM0 and FTM2 are fully compatible with the TPM.

FTM	Functions	Default	Alternate	
FTM0	Channel 0	PTA0/FTM0CH0	PTA5/FTM0CH0	
	Channel 1	PTA1/FTM0CH1	PTA4/FTM0CH1	
	alternate clock	PTA5/TCLK0		
FTM2	Channel 0	PTC0/FTM2CH0		
	Channel 1	PTC1/FTM2CH1		
	Channel 2	PTC2/FTM2CH2		
	Channel 3	PTC3/FTM2CH3		
	Channel 4	PTB4/FTM2CH4		
	Channel 5	PTB5/FTM2CH5		
	alternate clock	PTB3/TCLK2		

Table 15-1. FTM module external signals

The memory map in this chapter shows the whole registers the FTM modules can support, but for this device, only the following registers take effect.

#### Table 15-2. FTM module registers

FTM	Registers
FTM0	SC, CNTH, CNTL, MODH, MODL, C0SC, C0VH, C0VL,C1SC, C1VH, C1VL
FTM2	All the FTM2 registers

# 15.2 Introduction

### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The FlexTimer module is a two to eight channel timer which supports input capture, output compare, and the generation of PWM signals to control electric motor and power management applications. The FTM time reference is a 16-bit unsigned counter.

# 15.2.1 FlexTimer philosophy

The FlexTimer is built upon a very simple timer used for many years on NXP's 8-bit microcontrollers, the HCS08 Timer PWM Module – TPM. The FlexTimer extends the functionality to meet the demands of motor control, digital lighting solutions, and power conversion, while providing low cost and backwards compatibility with the TPM module.

All of the features common with the TPM module have fully backwards compatible register assignments and the FlexTimer can use code on the same core platform without change to perform the same functions.

# 15.2.2 Features

The FTM features include:

- Selectable FTM source clock:
  - Source clock can be the system clock, the fixed frequency clock, or an external clock
  - Fixed frequency clock is an additional clock input to allow the selection of an on chip clock source other than the system clock
  - Selecting external clock connects FTM clock to a chip level input pin therefore allowing to synchronize the FTM counter with an off chip clock source
- Prescaler divide-by 1, 2, 4, 8, 16, 32, 64, or 128
- FTM has a 16-bit counter

- It can be a free-running counter or a counter with selectable final value
- The counting can be up or up-down
- Each channel can be configured for input capture, output compare, or edge-aligned PWM mode
- In input capture mode:
  - The capture can occur on rising edges, falling edges or both edges
- In output compare mode the output signal can be set, cleared, or toggled on match
- All channels can be configured for center-aligned PWM mode
- The generation of an interrupt per channel
- The generation of an interrupt when the counter overflows
- Backwards compatible with TPM

# 15.2.3 Modes of operation

When the MCU is in active BDM background or BDM foreground mode, the FTM temporarily suspends all counting until the MCU returns to normal user operating mode. During stop mode, all FTM input clocks are stopped, so the FTM is effectively disabled until clocks resume. During wait mode, the FTM continues to operate normally. If the FTM does not need to produce a real time reference or provide the interrupt sources needed to wake the MCU from wait mode, the power can then be saved by disabling FTM functions before entering wait mode.

### 15.2.4 Block diagram

The FTM uses one input/output (I/O) pin per channel, CHn (FTM channel (n)) where n is the channel number (0–7).

The following figure shows the FTM structure. The central component of the FTM is the 16-bit counter with programmable final value and its counting can be up or up-down.

### Signal description

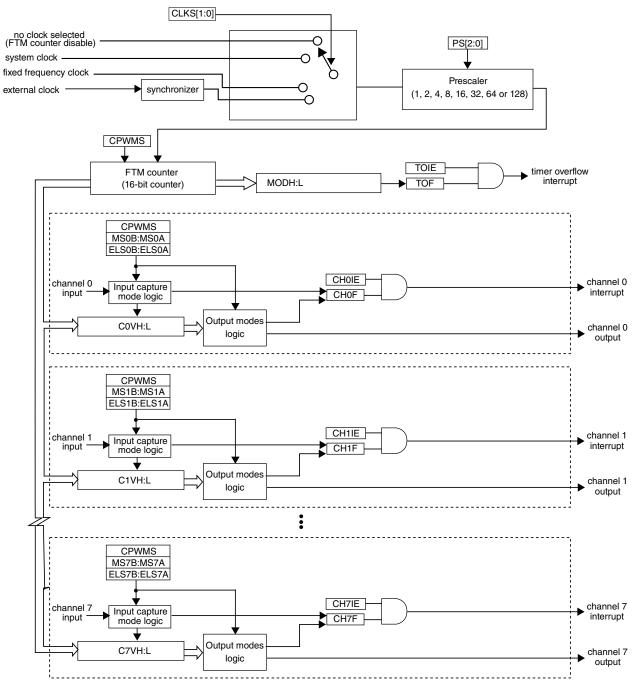

Figure 15-1. FTM block diagram

# 15.3 Signal description

The following table shows the user-accessible signals for the FTM.

Name	Function
EXTCLK	External clock – FTM external clock can be selected to drive the FTM counter.
CHn <sup>1</sup>	Channel (n) – I/O pin associated with FTM channel (n).

Table 15-3. Signal properties

1. n = channel number (0 to 7)

### 15.3.1 EXTCLK — FTM external clock

The external clock input signal is used as the FTM counter clock if selected by CLKS[1:0] bits in the SC register. This clock signal must not exceed 1/4 of system clock frequency. The FTM counter prescaler selection and settings are also used when an external clock is selected.

### 15.3.2 CHn — FTM channel (n) I/O pin

Each FTM channel can be configured to operate either as input or output. The direction associated with each channel, input or output, is selected according to the mode assigned for that channel.

### 15.4 Memory map and register definition

This section provides a detailed description of all FTM registers.

### 15.4.1 Module memory map

This section presents a high-level summary of the FTM registers and how they are mapped.

### 15.4.2 Register descriptions

This section consists of register descriptions in address order.

### FTM memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

#### FTM memory map (continued)

### 15.4.3 Status and Control (FTMx\_SC)

SC contains the overflow status flag and control bits used to configure the interrupt enable, FTM configuration, clock source, and prescaler factor. These controls relate to all channels within this module.

#### FTMx\_SC field descriptions

Field	Description
7	Timer Overflow Flag
TOF	Set by hardware when the FTM counter passes the value in the Counter Modulo registers. The TOF bit is cleared by reading the SC register while TOF is set and then writing a 0 to TOF bit. Writing a 1 to TOF has no effect.
	If another FTM overflow occurs between the read and write operations, the write operation has no effect; therefore, TOF remains set indicating an overflow has occurred. In this case a TOF interrupt request is not lost due to the clearing sequence for a previous TOF.
	0 FTM counter has not overflowed.
	1 FTM counter has overflowed.
6 TOIE	Timer Overflow Interrupt Enable
	Enables FTM overflow interrupts.
	0 Disable TOF interrupts. Use software polling.
	1 Enable TOF interrupts. An interrupt is generated when TOF equals one.

Table continues on the next page...

#### MC9S08PL16S Reference Manual, Rev. 3, 06/2020

Field	Description
5	Center-aligned PWM Select
CPWMS	Selects CPWM mode. This mode configures the FTM to operate in up-down counting mode.
	0 FTM counter operates in up counting mode.
	1 FTM counter operates in up-down counting mode.
4–3	Clock Source Selection
CLKS	Selects one of the three FTM counter clock sources.
	00 No clock selected (this in effect disables the FTM counter).
	01 System clock is selected for FTM0, system clock divided by 2 is selected for FTM2
	10 Fixed frequency clock
	11 External clock
PS	Prescale Factor Selection
	Selects one of 8 division factors for the clock source selected by CLKS. The new prescaler factor affects the clock source on the next system clock cycle after the new value is updated into the register bits.
	000 Divide by 1
	001 Divide by 2
	010 Divide by 4
	011 Divide by 8
	100 Divide by 16
	101 Divide by 32

#### FTMx\_SC field descriptions (continued)

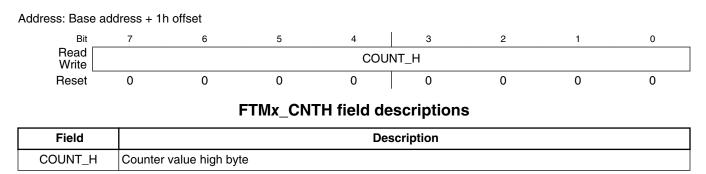

### 15.4.4 Counter High (FTMx\_CNTH)

The Counter registers contain the high and low bytes of the counter value. Reading either byte latches the contents of both bytes into a buffer where they remain latched until the other half is read. This allows coherent 16-bit reads in either big-endian or little-endian order which makes this more friendly to various compiler implementations. The coherency mechanism is automatically restarted by an MCU reset or any write to the Status and Control register.

Writing any value to COUNT\_H or COUNT\_L updates the FTM counter with its initial 16-bit value (all zeroes) and resets the read coherency mechanism, regardless of the data involved in the write.

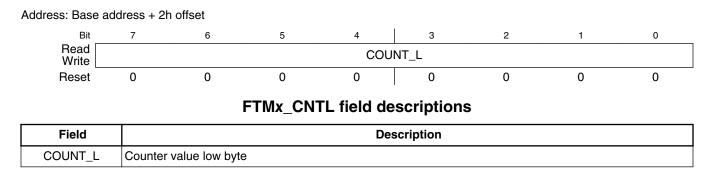

When BDM is active, the FTM counter is frozen (this is the value that you may read); the read coherency mechanism is frozen such that the buffer latches remain in the state they were in when the BDM became active, even if one or both counter bytes are read while

BDM is active. This assures that if you were in the middle of reading a 16-bit register when BDM became active, it reads the appropriate value from the other half of the 16-bit value after returning to normal execution.

### 15.4.5 Counter Low (FTMx\_CNTL)

See the description for the Counter High register.

### 15.4.6 Modulo High (FTMx\_MODH)

The Modulo registers contain the high and low bytes of the modulo value for the FTM counter. After the FTM counter reaches the modulo value, the overflow flag (TOF) becomes set at the next clock, and the next value of FTM counter depends on the selected counting method (Counter).

Writing to either byte latches the value into a buffer. The register is updated with the value of their write buffer according to Update of the registers with write buffers.

This write coherency mechanism may be manually reset by writing to the SC register whether BDM is active or not.

MC9S08PL16S Reference Manual, Rev. 3, 06/2020

#### Memory map and register definition

When BDM is active, this write coherency mechanism is frozen such that the buffer latches remain in the state they were in when the BDM became active, even if one or both bytes of the modulo register are written while BDM is active. Any write to the modulo register bypasses the buffer latches and directly writes to the modulo register while BDM is active.

It is recommended to initialize the FTM counter, by writing to CNTH or CNTL, before writing to the FTM modulo register to avoid confusion about when the first counter overflow will occur.

#### FTMx\_CnSC field descriptions (continued)

### 15.4.9 Channel Value High (FTMx\_CnVH)

These registers contain the captured FTM counter value of the input capture function or the match value for the output modes.

In input capture mode, reading a single byte in CnV latches the contents into a buffer where they remain latched until the other byte is read. This latching mechanism also resets, or becomes unlatched, when the CnSC register is written whether BDM mode is active or not. Any write to the channel registers is ignored during this mode.

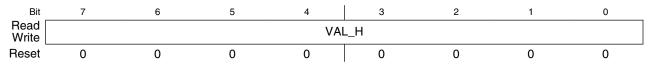

When BDM is active, the read coherency mechanism is frozen such that the buffer latches remain in the state they were in when the BDM became active, even if one or both bytes of the channel value register are read while BDM is active. This ensures that if you were in the middle of reading a 16-bit register when BDM became active, it reads the appropriate value from the other half of the 16-bit value after returning to normal execution. Any read of the CnV registers in BDM mode bypasses the buffer latches and returns the value of these registers and not the value of their read buffer.

In output modes, writing to CnV latches the value into a buffer. The registers are updated with the value of their write buffer according to Update of the registers with write buffers.

This write coherency mechanism may be manually reset by writing to the CnSC register whether BDM mode is active or not.

When BDM is active, the write coherency mechanism is frozen such that the buffer latches remain in the state they were in when the BDM became active even if one or both bytes of the channel value register are written while BDM is active. Any write to the CnV registers bypasses the buffer latches and writes directly to the register while BDM is active. The values written to the channel value registers while BDM is active are used in output modes operation after normal execution resumes. Writes to the channel value registers while BDM is active do not interfere with the partial completion of a coherency sequence. After the write coherency mechanism has been fully exercised, the channel value registers are updated using the buffered values while BDM was not active.

FTMx\_CnVL field descriptions (continued)

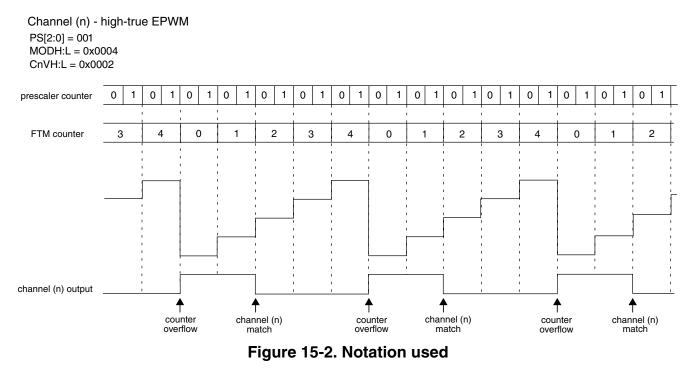

Field

Description

### **15.5 Functional Description**

The following sections describe the FTM features.

The notation used in this document to represent the counters and the generation of the signals is shown in the following figure.

### 15.5.1 Clock Source

FTM module has only one clock domain that is the system clock.

### 15.5.1.1 Counter Clock Source

The CLKS[1:0] bits in the SC register select one of three possible clock sources for the FTM counter or disable the FTM counter. After any MCU reset, CLKS[1:0] = 0:0 so no clock source is selected.

The CLKS[1:0] bits may be read or written at any time. Disabling the FTM counter by writing 0:0 to the CLKS[1:0] bits does not affect the FTM counter value or other registers.

The fixed frequency clock is an alternative clock source for the FTM counter that allows the selection of a clock other than the system clock or an external clock. This clock input is defined by chip integration. Refer to chip specific documentation for further information. Due to FTM hardware implementation limitations, the frequency of the fixed frequency clock must not exceed the system clock frequency.

The external clock passes through a synchronizer clocked by the system clock to ensure that counter transitions are properly aligned to system clock transitions. Therefore, to meet the Nyquist criteria and account for jitter, the frequency of the external clock source must not exceed 1/4 of the system clock frequency.

# 15.5.2 Prescaler

The selected counter clock source passes through a prescaler that is a 7-bit counter. The value of the prescaler is selected by the PS[2:0] bits. The following figure shows an example of the prescaler counter and FTM counter.

EPWM																		
PS[2:0] = 001 MODH:L = 0x0003																		
selected input clock																		
prescaler counter	1	0	1	0	1	0	1	0	1	0	1	0	1	0	1	0	1	0
FTM counter	0		1	2	2	:	3		0	1		:	2	3	3	(	)	1

Figure 15-3. Example of the prescaler counter

# 15.5.3 Counter

The FTM has a 16-bit counter that is used by the channels either for input or output modes. The FTM counter clock is the selected clock divided by the prescaler (see Prescaler).

The FTM counter has these modes of operation:

- up counting (see Up counting)
- up-down counting (see Up-down counting)

### 15.5.3.1 Up counting

Up counting is selected when (CPWMS = 0).

The starting value of the count is 0x0000 and MODH:L defines the final value of the count; see the following figure. The value of 0x0000 is loaded into the FTM counter, and the counter increments until the value of MODH:L is reached, at which point the counter is reloaded with 0x0000.

The FTM period when using up counting is (MODH:L + 0x0001) × period of the FTM counter clock.

The TOF bit is set when the FTM counter changes from MODH:L to 0x0000.

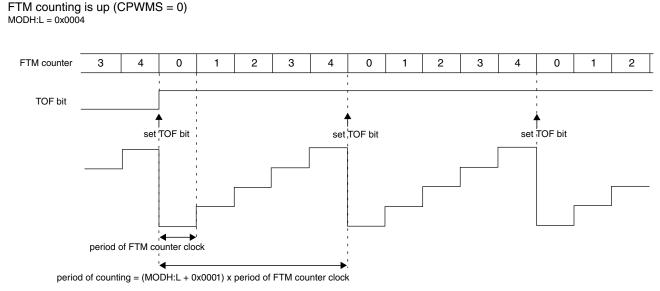

Figure 15-4. Example of FTM up counting

### 15.5.3.2 Up-down counting

Up-down counting is selected when (CPWMS = 1).

The starting value of the count is 0x0000 and MODH:L defines the final value of the count. The value of 0x0000 is loaded into the FTM counter, and the counter increments until the value of MODH:L is reached, at which point the counter is decremented until it returns to the value of 0x0000 and the up-down counting restarts.

The FTM period when using up-down counting is  $2 \times (MODH:L) \times period of the FTM counter clock.$ 

The TOF bit is set when the FTM counter changes from MODH:L to (MODH:L - 1).

FTM counting is up-down MODH:L = 0x0004

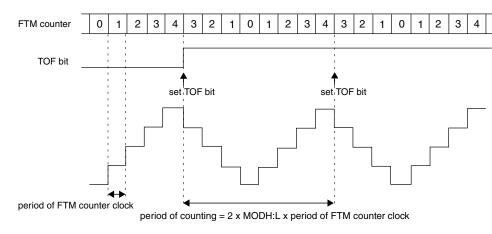

Figure 15-5. Example of up-down counting

### 15.5.3.3 Free running counter

If (MODH:L = 0x0000 or MODH:L = 0xFFFF), the FTM counter is a free running counter. In this case, the FTM counter runs free from 0x0000 through 0xFFFF and the TOF bit is set when the FTM counter changes from 0xFFFF to 0x0000 See the following figure.

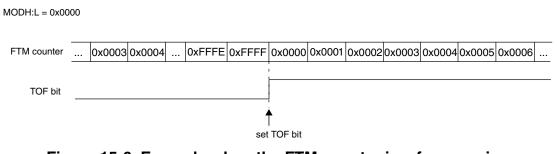

Figure 15-6. Example when the FTM counter is a free running

### 15.5.3.4 Counter reset

Any write to CNTH or CNTL register resets the FTM counter to the value of 0x0000 and the channels output to its initial value, except for channels in output compare mode.

### 15.5.4 Input capture mode

The input capture mode is selected when (CPWMS = 0), (MSnB:MSnA = 0:0), and (ELSnB:ELSnA  $\neq$  0:0).

#### Functional Description

When a selected edge occurs on the channel input, the current value of the FTM counter is captured into the CnVH:L registers. At the same time, the CHnF bit is set and the channel interrupt is generated if enabled by CHnIE = 1. See the following figure.

When a channel is configured for input capture, the CHn pin is an edge-sensitive input. ELSnB:ELSnA control bits determine which edge, falling or rising, triggers input-capture event. Note that the maximum frequency for the channel input signal to be detected correctly is system clock divided by four, which is required to meet Nyquist criteria for signal sampling.

When either half of the 16-bit capture register (CnVH:L) is read, the other half is latched into a buffer to support coherent 16-bit access in big-endian or little-endian order. This read coherency mechanism can be manually reset by writing to CnSC register.

Writes to the CnVH:L registers are ignored in input capture mode.

While in BDM, the input capture function works as configured. When a selected edge event occurs, the FTM counter value, which is frozen because of BDM, is captured into the CnVH:L registers and the CHnF bit is set.

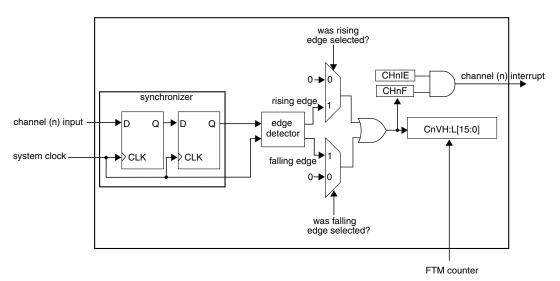

Figure 15-7. Input capture mode

The input signal is always delayed three rising edges of the system clock; that is, two rising edges to the synchronizer plus one more rising edge to the edge detector. In other words, the CHnF bit is set on the third rising edge of the system clock after a valid edge occurs on the channel input.

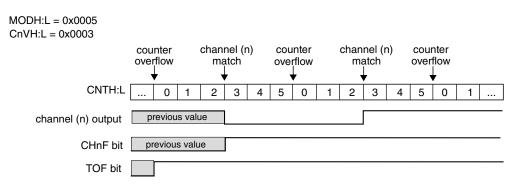

### 15.5.5 Output compare mode

The output compare mode is selected when (CPWMS = 0) and (MSnB:MSnA = 0:1).

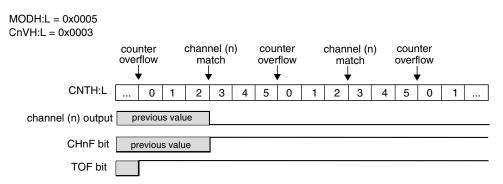

In output compare mode, the FTM can generate timed pulses with programmable position, polarity, duration, and frequency. When the counter matches the value in the CnVH:CnVL registers of an output compare channel, the channel (n) output can be set, cleared, or toggled.

When a channel is initially configured to toggle mode, the previous value of the channel output is held until the first output compare event occurs.

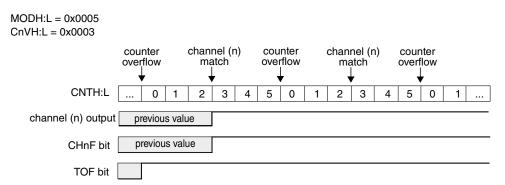

The CHnF bit is set and the channel (n) interrupt is generated (if CHnIE = 1) at the channel (n) match (FTM counter = CnVH:CnVL).

# Figure 15-8. Example of the output compare mode when the match toggles the channel output

# Figure 15-9. Example of the output compare mode when the match clears the channel output

# Figure 15-10. Example of the output compare mode when the match sets the channel output

#### MC9S08PL16S Reference Manual, Rev. 3, 06/2020

#### **Functional Description**

It is possible to use the output compare mode with (ELSnB:ELSnA = 0:0). In this case, when the counter reaches the value in the CnVH:CnVL registers, the CHnF bit is set and the channel (n) interrupt is generated, if CHnIE = 1. However, the channel (n) output is not modified and controlled by FTM.

### 15.5.6 Edge-aligned PWM (EPWM) mode

The edge-aligned mode is selected when all of the following apply:

- (CPWMS = 0)
- (MSnB = 1)

The EPWM period is determined by (MODH:L + 0x0001) and the pulse width (duty cycle) is determined by (CnVH:L).

The CHnF bit is set and the channel (n) interrupt is generated (if CHnIE = 1) at the channel (n) match (FTM counter = CnVH:L), that is, at the end of the pulse width.

This type of PWM signal is called edge-aligned because the leading edges of all PWM signals are aligned with the beginning of the period, which is the same for all channels within an FTM.

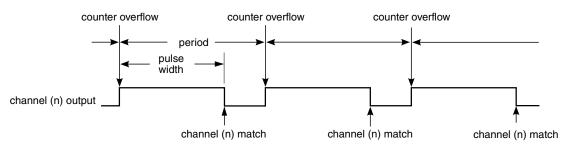

Figure 15-11. EPWM period and pulse width with ELSnB:ELSnA = 1:0

If (ELSnB:ELSnA = 0:0) when the counter reaches the value in the CnVH:L registers, the CHnF bit is set and the channel (n) interrupt is generated (if CHnIE = 1), however, the channel (n) output is not controlled by FTM.

If (ELSnB:ELSnA = 1:0), then the channel (n) output is forced high at the counter overflow, when the value of 0x0000 is loaded into the FTM counter. Additionally, it is forced low at the channel (n) match, when the FTM counter = CnVH:L. See the following figure.

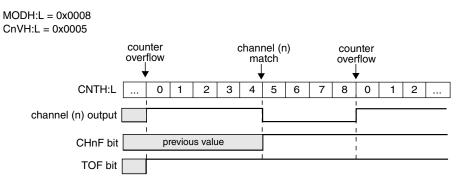

Figure 15-12. EPWM signal with ELSnB:ELSnA = 1:0

If (ELSnB:ELSnA = X:1), then the channel (n) output is forced low at the counter overflow, when the value of 0x0000 is loaded into the FTM counter. Additionally, it is forced high at the channel (n) match, when the FTM counter = CnVH:L. See the following figure.

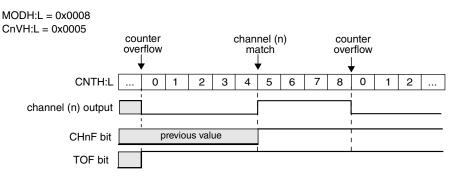

Figure 15-13. EPWM signal with ELSnB:ELSnA = X:1

If (CnVH:L = 0x0000), then the channel (n) output is a 0% duty cycle EPWM signal and CHnF bit is not set, even when there is the channel (n) match. If (CnVH:L > MODH:L), then the channel (n) output is a 100% duty cycle EPWM signal and CHnF bit is not set, even when there is the channel (n) match. Therefore, MODH:MODL must be less than 0xFFFF in order to get a 100% duty cycle EPWM signal.

# 15.5.7 Center-aligned PWM (CPWM) mode

The center-aligned mode is selected when:

• (CPWMS = 1)

The CPWM pulse width (duty cycle) is determined by  $2 \times (CnVH:L)$ . The period is determined by  $2 \times (MODH:L)$ . See the following figure. MODH:L must be kept in the range of 0x0001 to 0x7FFF because values outside this range can produce ambiguous results.

In the CPWM mode, the FTM counter counts up until it reaches MODH:L and then counts down until it reaches the value of 0x0000.

#### MC9S08PL16S Reference Manual, Rev. 3, 06/2020

#### Functional Description

The CHnF bit is set and channel (n) interrupt is generated (if CHnIE = 1) at the channel (n) match (FTM counter = CnVH:L) when the FTM counting is down, at the begin of the pulse width, and when the FTM counting is up, at the end of the pulse width.

This type of PWM signal is called center-aligned because the pulse width centers for all channels are aligned with the value of 0x0000.

The other channel modes are not compatible with the up-down counter (CPWMS = 1). Therefore, all FTM channels must be used in CPWM mode when (CPWMS = 1).

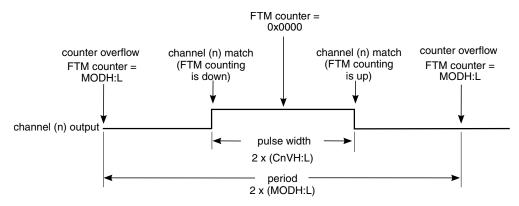

Figure 15-14. CPWM period and pulse width with ELSnB:ELSnA = 1:0

If (ELSnB:ELSnA = 0:0) when the counter reaches the value in the CnVH:L registers, the CHnF bit is set and the channel (n) interrupt is generated (if CHnIE = 1), however the channel (n) output is not controlled by FTM.

If (ELSnB:ELSnA = 1:0), then the channel (n) output is forced high at the channel (n) match (FTM counter = CnVH:L) when counting down, and it is forced low at the channel (n) match when counting up; see the following figure.

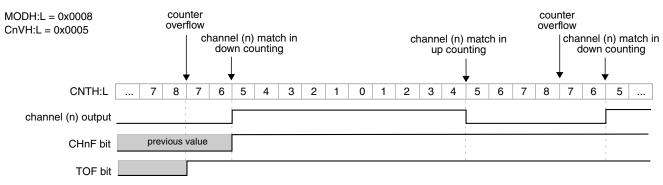

Figure 15-15. CPWM signal with ELSnB:ELSnA = 1:0

If (ELSnB:ELSnA = X:1), then the channel (n) output is forced low at the channel (n) match (FTM counter = CnVH:L) when counting down, and it is forced high at the channel (n) match when counting up; see the following figure.

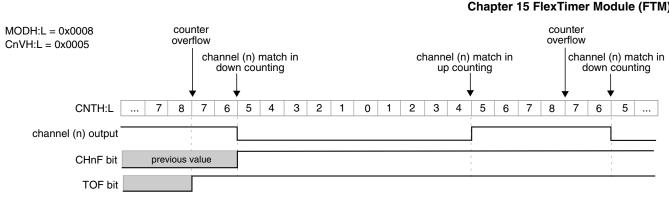

Figure 15-16. CPWM signal with ELSnB:ELSnA = X:1

If (CnVH:L = 0x0000) or (CnVH:L is a negative value, that is, CnVH[7] = 1) then the channel (n) output is a 0% duty cycle CPWM signal and CHnF bit is not set even when there is the channel (n) match.

If (CnVH:L is a positive value, that is, CnVH[7] = 0), (CnVH:L  $\ge$  MODH:L), and (MODH:L  $\neq$  0x0000), then the channel (n) output is a 100% duty cycle CPWM signal and CHnF bit is not set even when there is the channel (n) match. This implies that the usable range of periods set by MODH:L is 0x0001 through 0x7FFE, or 0x7FFF if you do not need to generate a 100% duty cycle CPWM signal. This is not a significant limitation because the resulting period is much longer than required for normal applications.

The CPWM mode must not be used when the FTM counter is a free running counter.

### 15.5.8 Update of the registers with write buffers

This section describes the updating of registers that have write buffers.

### 15.5.8.1 MODH:L registers

If (CLKS[1:0] = 0:0), then MODH:L registers are updated when their second byte is written.

If (CLKS[1:0] ≠ 0:0), then MODH:L registers are updated according to the CPWMS bit:

- If the selected mode is not CPWM mode, then MODH:L registers are updated after both bytes have been written and the FTM counter changes from (MODH:L) to (all zeroes). If the FTM counter is a free-running counter, then this update is made when the FTM counter changes from 0xFFFF to 0x0000.
- If the selected mode is CPWM mode, then MODH:L registers are updated after both bytes have been written and the FTM counter changes from MODH:L to (MODH:L - 0x0001).

MC9S08PL16S Reference Manual, Rev. 3, 06/2020

### 15.5.8.2 CnVH:L registers

If (CLKS[1:0] = 0:0), then CnVH:L registers are updated when their second byte is written.

If (CLKS[1:0]  $\neq$  0:0), then CnVH:L registers are updated according to the selected mode:

- If the selected mode is output compare mode, then CnVH:L registers are updated after their second byte is written and on the next change of the FTM counter.
- If the selected mode is EPWM mode, the CnVH:L registers are updated after both bytes have been written and the FTM counter changes from MODH:L to all zeroes. If the FTM counter is a free running counter, then this update is made when the FTM counter changes from 0xFFFF to 0x0000.
- If the selected mode is CPWM mode, then CnVH:L registers are updated after both bytes have been written and the FTM counter changes from MODH:L to (MODH:L - 0x0001).

### 15.5.9 BDM mode

When BDM mode is active, the FlexTimer counter and the channels output are frozen.

However, the value of FlexTimer counter or the channels output are modified in BDM mode when:

• A write of any value to the CNTH or CNTL registers (Counter reset) resets the FTM counter to the value of 0x0000 and the channels output to their initial value, except for channels in output compare mode.

# 15.6 Reset overview

The FTM is reset whenever any chip reset occurs.

When the FTM exits from reset:

- The FTM counter and the prescaler counter are zero and are stopped (CLKS[1:0] = 0b00)
- The timer overflow interrupt is zero (Timer overflow interrupt)
- The channels interrupts are zero (Channel (n) interrupt)

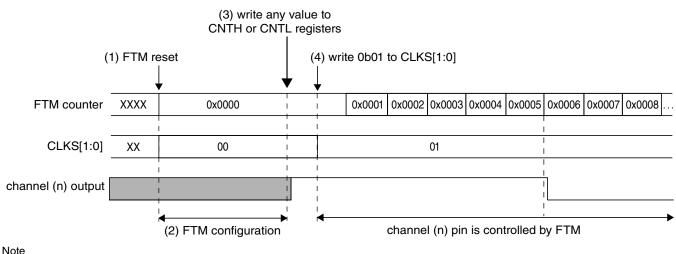

- The channels are in input capture mode (Input capture mode)
- The channels outputs are zero
- The channels pins are not controlled by FTM (ELS(n)B:ELS(n)A = 0b00). See table "Mode, Edge, and Level Selection"

The following figure shows the FTM behavior after the reset. At the reset (item 1), the FTM counter is disabled (see table "FTM Clock Source Selection"), its value is updated to zero and the pins are not controlled by FTM (table "Mode, Edge, and Level Selection").

After the reset, the FTM should be configured (item 2). It is necessary to define the FTM counter mode, the FTM counting limit (MODH:L registers value), the channels mode and CnVH:L registers value according to the channels mode.

Because of this, you should write any value to CNTH or CNTL registers (item 3). This write updates the FTM counter with the value of 0x0000 and the channels output with its initial value (except for channels in output compare mode) (Counter reset).

The next step is to select the FTM counter clock by the CLKS[1:0] bits (item 4). It is important to highlight that the pins are controlled only by FTM when CLKS[1:0] bits are different from zero (table "Mode, Edge, and Level Selection").

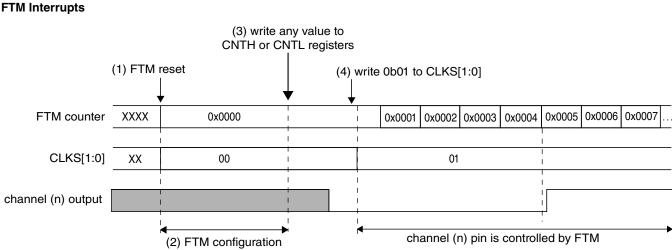

– Channel (n) is in high-true EPWM mode with 0 < C(n)VH:L < MODH:L</p>

- C(n)VH:L = 0x0005

### Figure 15-17. FTM behavior after the reset when the channel (n) is in EPWM mode

The following figure shows an example when the channel (n) is in output compare mode and the channel (n) output is toggled when there is a match. In the output compare mode, the channel output is not updated to its initial value when there is a write to CNTH or CNTL registers (item 3).

#### Note

- Channel (n) is in output compare and the channel (n) output is toggled when there is a match

-C(n)VH:L = 0x0004

# Figure 15-18. FTM behavior after the reset when the channel (n) is in output compare mode

### 15.7 FTM Interrupts

### 15.7.1 Timer overflow interrupt

The timer overflow interrupt is generated when (TOIE = 1) and (TOF = 1).

### 15.7.2 Channel (n) interrupt

The channel (n) interrupt is generated when (CHnIE = 1) and (CHnF = 1).

# Chapter 16 8-bit modulo timer (MTIM)

# 16.1 Chip specific MTIM information

The modulo timer module (MTIM) provides a circuit of selectable clock sources and a programmable interrupt. The MTIM module contains a 8-bit modulo counter, which can operate as a free-running counter or a modulo counter. A timer overflow interrupt can be enabled to generate periodic interrupts for time-based software events. MTIM module may use external clock source. Following table summarizes the external signals of MTIM modules.

Table 16	-1. MTIM	clocks

MTIM Module Clock Interface	Chip Specific Clock Source
Bus clock (BUSCLK)	BUSCLK
Fixed frequncy clock (XCLK)	FFCLK
TCLK	TCLK0 for MTIM0 and TCLK2 for MTIM1

The MTIM module can be used for ADC hardware trigger, refer to System Control for more details.

# 16.2 Introduction

The MTIM is a simple 8-bit timer with several software selectable clock sources and a programmable interrupt.

For MCUs that have more than one MTIM, the MTIMs are collectively called MTIMx. For example, MTIMx for an MCU with two MTIMs would refer to MTIM0 and MTIM1. For MCUs that have exactly one MTIM, it is always referred to as MTIM.

# 16.3 Features

Timer system features include:

- 8-bit up-counter:
  - Free-running or 8-bit modulo limit
  - Software controllable interrupt on overflow
  - Counter reset bit (TRST)
  - Counter stop bit (TSTP)
- Four software selectable clock sources for input to prescaler:
  - System bus clock rising edge
  - Fixed frequency clock (XCLK) rising edge
  - External clock source on the TCLK pin rising edge
  - External clock source on the TCLK pin falling edge
- Nine selectable clock prescale values:
  - Clock source divide by 1, 2, 4, 8, 16, 32, 64, 128, or 256

### 16.4 Modes of operation

This section defines the MTIM's operation in stop, wait, and background debug modes.

### 16.4.1 MTIM in wait mode

The MTIM continues to run in wait mode if enabled before executing the WAIT instruction. Therefore, the MTIM can be used to bring the MCU out of wait mode if the timer overflow interrupt is enabled. For lowest possible current consumption, the MTIM must be stopped by software if not needed as an interrupt source during wait mode.

### 16.4.2 MTIM in stop mode

The MTIM is disabled in stop mode, regardless of the settings before executing the STOP instruction. Therefore, the MTIM cannot be used as a wakeup source from stop modes.

If stop3 is exited with a reset, the MTIM will be put into its reset state. If stop3 is exited with an interrupt, the MTIM continues from the state it was in when stop3 was entered. If the counter was active upon entering stop3, the count will resume from the current value.

### 16.4.3 MTIM in active background mode

The MTIM suspends all counting until the microcontroller returns to normal user operating mode. Counting resumes from the suspended value as long as an MTIM reset did not occur, MTIM\_SC[TRST] written to a 1 or MTIM\_MOD written.

# 16.5 Block diagram

The block diagram for the modulo timer module is shown in the following figure.

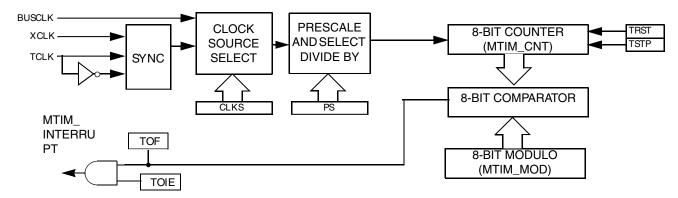

Figure 16-1. Modulo timer (MTIM) block diagram

# 16.6 External signal description

The MTIM includes one external signal, TCLK, used to input an external clock when selected as the MTIM clock source. The signal properties of TCLK are shown in the following table.

Table 16-2.	MTIM externa	l signal
-------------	--------------	----------

Signal	Function	I/O
TCLK	External clock source input into MTIM	1

The TCLK input must be synchronized by the bus clock. Also, variations in duty cycle and clock jitter must be accommodated. Therefore, the TCLK signal must be limited to one-fourth of the bus frequency.

The TCLK pin can be muxed with a general-purpose port pin.

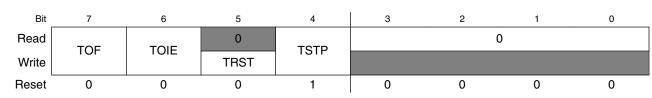

# 16.7 Register definition

#### **MTIM memory map**

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
18	MTIM Status and Control Register (MTIM0_SC)	8	R/W	10h	16.7.1/252
19	MTIM Clock Configuration Register (MTIM0_CLK)	8	R/W	00h	16.7.2/253
1A	MTIM Counter Register (MTIM0_CNT)	8	R	00h	16.7.3/254
1B	MTIM Modulo Register (MTIM0_MOD)	8	R/W	00h	16.7.4/254

### 16.7.1 MTIM Status and Control Register (MTIMx\_SC)

MTIM\_SC contains the overflow status flag and control bits that are used to configure the interrupt enable, reset the counter, and stop the counter.

Address: 18h base + 0h offset = 18h

#### MTIMx\_SC field descriptions

Field	Description
7	MTIM Overflow Flag
TOF	This bit is set when the MTIM counter register overflows to 0x00 after reaching the value in the MTIM modulo register. Clear TOF by reading the MTIM_SC register while TOF is set, then write a 0 to TOF. TOF is also cleared when TRST is written to a 1 or when any value is written to the MTIM_MOD register.
	0 MTIM counter has not reached the overflow value in the MTIM modulo register.
	1 MTIM counter has reached the overflow value in the MTIM modulo register.
6 TOIE	MTIM Overflow Interrupt Enable
	This read/write bit enables MTIM overflow interrupts. If TOIE is set, then an interrupt is generated when TOF = 1. Reset clears TOIE. Do not set TOIE if TOF = 1. Clear TOF first, then set TOIE.
	0 TOF interrupts are disabled. Use software polling.
	1 TOF interrupts are enabled.
5 TRST	MTIM Counter Reset
	When a 1 is written to this write-only bit, the MTIM counter register resets to 0x00 and TOF is cleared. Reading this bit always returns 0.

Table continues on the next page...

Field	Description
	0 No effect. MTIM counter remains at current state.
	1 MTIM counter is reset to 0x00.
4	MTIM Counter Stop
TSTP	When set, this read/write bit stops the MTIM counter at its current value. Counting resumes from the current value when TSTP is cleared. Reset sets TSTP to prevent the MTIM from counting.
	0 MTIM counter is active.
	1 MTIM counter is stopped.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

### MTIMx\_SC field descriptions (continued)

#### MTIM Clock Configuration Register (MTIMx\_CLK) 16.7.2

MTIM\_CLK contains the clock select bits (CLKS) and the prescaler select bits (PS).

Address: 18h base + 1h offset = 19h

Bit	7	6	5	4	3	2	1	0
Read		0	CI	KS		P	S	
Write			-			-	-	
Reset	0	0	0	0	0	0	0	0

#### MTIMx\_CLK field descriptions

Field	Description
7–6	This field is reserved.
Reserved	This read-only field is reserved and always has the value 0.
5–4	Clock Source Select
CLKS	
	These two read/write bits select one of four different clock sources as the input to the MTIM prescaler. Changing the clock source while the counter is active does not clear the counter. The count continues with
	the new clock source. Reset clears CLKS to 000b.
	00 Encoding 0. Bus clock (BUSCLK).
	01 Encoding 1. Fixed-frequency clock (XCLK).
	10 Encoding 2. External source (TCLK pin), falling edge.
	11 Encoding 3. External source (TCLK pin), rising edge.
PS	Clock Source Prescaler
	These four read/write bits select one of nine outputs from the 8-bit prescaler. Changing the prescaler value
	while the counter is active does not clear the counter. The count continues with the new prescaler value.
	Reset clears PS to 0000b.
	0000 Encoding 0. MTIM clock source.
	0001 Encoding 1. MTIM clock source/2.
	0010 Encoding 2. MTIM clock source/4.
	0011 Encoding 3. MTIM clock source/8.
	Table continues on the next page

Table continues on the next page...

	Others	Default to MTIM clock source/256.					

#### MTIMx\_CLK field descriptions (continued)

## 16.7.3 MTIM Counter Register (MTIMx\_CNT)

MTIM\_CNT is the read-only value of the current MTIM count of the 8-bit counter.

Address: 18h base + 2h offset = 1Ah

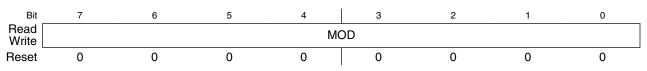

#### MTIMx\_CNT field descriptions

Field	Description
COUNT	MTIM Count
	These eight read-only bits contain the current value of the 8-bit counter. Writes have no effect to this register. Reset clears the count to 0x00.

### 16.7.4 MTIM Modulo Register (MTIMx\_MOD)

Address: 18h base + 3h offset = 1Bh

#### MTIMx\_MOD field descriptions

Field	Description
	MTIM Modulo These eight read/write bits contain the modulo value used to reset the count and set TOF. A value of 0x00 puts the MTIM in free-running mode. Writing to MTIM_MOD resets the COUNT to 0x00 and clears TOF. Reset sets the modulo to 0x00.

# 16.8 Functional description

The MTIM consists of a main 8-bit up-counter with an 8-bit modulo register, a clock source selector, and a prescaler block with nine selectable values. The module also contains software-selectable interrupt logic.

The MTIM counter (MTIM\_CNT) has three modes of operation: stopped, free-running, and modulo. Out of reset, the counter is stopped. If the counter is started without writing a new value to the modulo register, then the counter will be in free-running mode. The counter is in modulo mode when a value other than 0x00 is in the modulo register while the counter is running.

After any MCU reset, the counter is stopped and reset to 0x00, and the modulus is set to 0x00. The bus clock is selected as the default clock source and the prescale value is divide by 1. To start the MTIM in free-running mode, simply write to the MTIM status and control register (MTIM\_SC), and clear the MTIM stop bit (TSTP).

Four clock sources are software selectable: the internal bus clock, the fixed frequency clock (XCLK), and an external clock on the TCLK pin, selectable as incrementing on either rising or falling edges. The MTIM clock select bits, CLKS1:CLKS0, in MTIM\_CLK are used to select the desired clock source. If the counter is active (SC[TSTP] = 0) when a new clock source is selected, the counter will continue counting from the previous value using the new clock source.

Nine prescale values are software selectable: clock source divided by 1, 2, 4, 8, 16, 32, 64, 128, or 256. The prescaler select bits (CLK[PS]) in MTIM\_CLK select the desired prescale value. If the counter is active (SC[TSTP] = 0) when a new prescaler value is selected, the counter will continue counting from the previous value using the new prescaler value.

The MTIM modulo register (MTIM\_MOD) allows the overflow compare value to be set to any value from 0x01 to 0xFF. Reset clears the modulo value to 0x00, which results in a free running counter.

When the counter is active (SC[TSTP] = 0), the counter increments at the selected rate until the count matches the modulo value. When these values match, the counter overflows to 0x00 and continues counting. The MTIM overflow flag (SC[TOF]) is set whenever the counter overflows. The flag sets on the transition from the modulo value to 0x00. Writing to MTIM\_MOD while the counter is active resets the counter to 0x00 and clears SC[TOF].

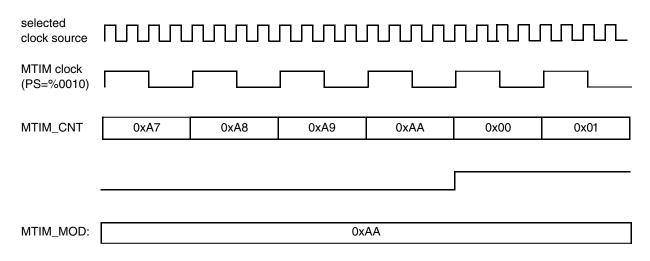

#### Functional description

Clearing SC[TOF] is a two-step process. The first step is to read the MTIM\_SC register while SC[TOF] is set. The second step is to write a 0 to SC[TOF]. If another overflow occurs between the first and second step, the clearing process is reset and SC[TOF] will remain set after the second step is performed. This will prevent the second occurrence from being missed. SC[TOF] is also cleared when a 1 is written to SC[TRST] or when any value is written to the MTIM\_MOD register.

The MTIM allows for an optional interrupt to be generated whenever SC[TOF] is set. To enable the MTIM overflow interrupt, set the MTIM overflow interrupt enable bit (SC[TOIE]). SC[TOIE] must never be written to a 1 while SC[TOF] = 1. Instead, SC[TOF] must be cleared first, then the SC[TOIE] can be set to 1.

## 16.8.1 MTIM operation example

This section shows an example of the MTIM operation as the counter reaches a matching value from the modulo register.

#### Figure 16-2. MTIM counter overflow example

In the above example, the selected clock source could be any of the four possible choices. The prescaler is set to CLK[PS] = 0010b or divide-by-4. The modulo value in the MTIM\_MOD register is set to 0xAA. When the counter, MTIM\_CNT, reaches the modulo value of 0xAA, it overflows to 0x00 and continues counting. The timer overflow flag, SC[TOF], sets when the counter value changes from 0xAA to 0x00. An MTIM overflow interrupt is generated when SC[TOF] is set, if SC[TOIE] = 1.

# Chapter 17 Real-time counter (RTC)

# 17.1 Chip specific RTC information

This device contains a Real-Time Counter (RTC) module, which can work with other peripherals like ADC and FTM to realize flexible trigger and capture functions, refer to System Control for more details.

The RTC has the following clock options:

RTC Module Clock Interface	Chip Specific Clock Source
Bus clock (BUS CLK)	BUSCLK
Internal LPO clock (LPO CLK)	LPOCLK (1 kHz)
Internal RC oscillator clock (IRC CLK)	ICSIRCLK (up to the 32 kHz)
External clock (EXT CLK)	OSCOUT

Table 17-1. RTC clock options

# 17.2 Introduction

The real-time counter (RTC) consists of one 16-bit counter, one 16-bit comparator, several binary-based and decimal-based prescaler dividers, three clock sources, one programmable periodic interrupt. This module can be used for time-of-day, calendar or any task scheduling functions. It can also serve as a cyclic wake-up from low-power modes, Stop and Wait without the need of external components.

# 17.3 Features

Features of the RTC module include:

• 16-bit up-counter

#### Features

- 16-bit modulo match limit
- Software controllable periodic interrupt on match
- Software selectable clock sources for input to prescaler with programmable 16 bit prescaler
  - OSC 32.768KHz nominal.
  - LPO (~1 kHz)
  - Bus clock
  - Internal reference clock

# 17.3.1 Modes of operation

This section defines the RTC operation in Stop, Wait, and Background Debug modes.

## 17.3.1.1 Wait mode

The RTC continues to run in Wait mode if enabled before executing the WAIT instruction. Therefore, the RTC can be used to bring the MCU out of Wait mode if the real-time interrupt is enabled. For lowest possible current consumption, the RTC must be stopped by software if not needed as an interrupt source during Wait mode.

## 17.3.1.2 Stop modes

The RTC continues to run in Stop mode if the RTC is enabled before executing the STOP instruction. Therefore, the RTC can be used to bring the MCU out of stop modes with no external components, if the real-time interrupt is enabled.

# 17.3.2 Block diagram

The block diagram for the RTC module is shown in the following figure.

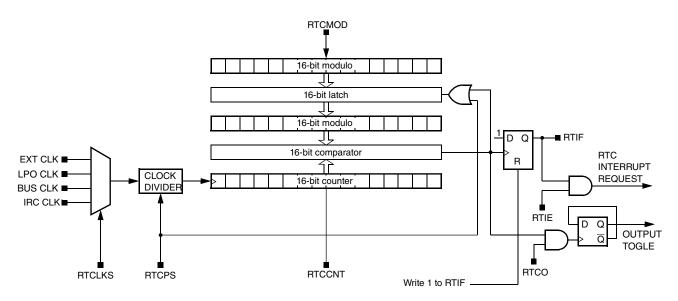

Figure 17-1. Real-time counter (RTC) block diagram

# 17.4 Register definition

The RTC includes a status and control register, a 16-bit counter register, and a 16-bit modulo register.

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
306A	RTC Status and Control Register 1 (RTC_SC1)	8	R/W	00h	17.4.1/260
306B	RTC Status and Control Register 2 (RTC_SC2)	8	R/W	00h	17.4.2/260
306C	RTC Modulo Register: High (RTC_MODH)	8	R/W	00h	17.4.3/261
306D	RTC Modulo Register: Low (RTC_MODL)	8	R/W	00h	17.4.4/262
306E	RTC Counter Register: High (RTC_CNTH)	8	R	00h	17.4.5/262
306F	RTC Counter Register: Low (RTC_CNTL)	8	R	00h	17.4.6/263

#### **RTC** memory map

# 17.4.1 RTC Status and Control Register 1 (RTC\_SC1)

### RTC\_SC1 contains the real-time interrupt status flag (RTIF).

Address: 306Ah base + 0h offset = 306Ah

Bit	7	6	5	4	3	2	1	0
Read Write	RTIF	RTIE	0	Reserved		(	)	
Reset	0	0	0	0	0	0	0	0

#### **RTC\_SC1** field descriptions

Field	Description
7 RTIF	Real-Time Interrupt Flag
	This status bit indicates the RTC counter register reached the value in the RTC modulo register. Writing a logic 0 has no effect. Writing a logic 1 clears the bit and the real-time interrupt request. Reset clears RTIF to 0.
	0 RTC counter has not reached the value in the RTC modulo register.
	1 RTC counter has reached the value in the RTC modulo register.
6 RTIE	Real-Time Interrupt Enable
	This read/write bit enables real-time interrupts. If RTIE is set, then an interrupt is generated when RTIF is set. Reset clears RTIE to 0.
	0 Real-time interrupt requests are disabled. Use software polling.
	1 Real-time interrupt requests are enabled.
5	This field is reserved.
Reserved	This read-only field is reserved and always has the value 0.
4 Reserved	This field is reserved.
Reserved	This field is reserved.
ricserved	This read-only field is reserved and always has the value 0.

## 17.4.2 RTC Status and Control Register 2 (RTC\_SC2)

RTC\_SC2 contains the clock select bits (RTCLKS) and the prescaler select bits (RTCPS).

Address: 306Ah base + 1h offset = 306Bh

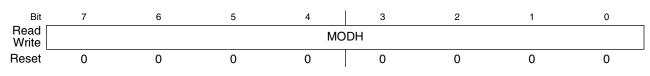

Field	Description
7–6 RTCLKS	Real-Time Clock Source Select
	These two read/write bits select the clock source input to the RTC prescaler. Changing the clock source clears the prescaler and RTCCNT counters. Reset clears RTCLKS to 00.
	00 External clock source.
	01 Real-time clock source is 1 kHz.
	10 Internal clock.
	11 Bus clock.
5–3	This field is reserved.
Reserved	This read-only field is reserved and always has the value 0.
RTCPS	Real-Time Clock Prescaler Select
	These four read/write bits select binary-based or decimal-based divide-by values for the clock source. Changing the prescaler value clears the prescaler and RTCCNT counters. Reset clears RTCPS to 0000.
	000 Off
	001 If RTCLKS = x0, it is 1; if RTCLKS = x1, it is 128.
	010 If RTCLKS = x0, it is 2; if RTCLKS = x1, it is 256.
	011 If RTCLKS = x0, it is 4; if RTCLKS = x1, it is 512.
	100 If RTCLKS = x0, it is 8; if RTCLKS = x1, it is 1024.
	101 If RTCLKS = x0, it is 16; if RTCLKS = x1, it is 2048.
	110 If RTCLKS = x0, it is 32; if RTCLKS = x1, it is 100.
	111 If RTCLKS = x0, it is 64; if RTCLKS = x1, it is 1000.

### **RTC\_SC2** field descriptions

## 17.4.3 RTC Modulo Register: High (RTC\_MODH)

RTC\_MODH, together with RTC\_MODL, indicates the value of the 16-bit modulo value.

Address: 306Ah base + 2h offset = 306Ch

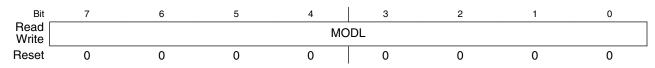

#### **RTC\_MODH** field descriptions

Field	Description
	RTC Modulo High These sixteen read/write bits, MODH and MODL, contain the modulo value used to reset the count to 0x0000 upon a compare match and set the RTIF status bit. A value of 0x00 of the MODH an MODL sets the RTIF bit on each rising edge of the prescaler output. Reset sets the modulo to 0x00.

## 17.4.4 RTC Modulo Register: Low (RTC\_MODL)

RTC\_MODL, together with RTC\_MODH, indicates the value of the 16-bit modulo value.

Address: 306Ah base + 3h offset = 306Dh

#### **RTC\_MODL** field descriptions

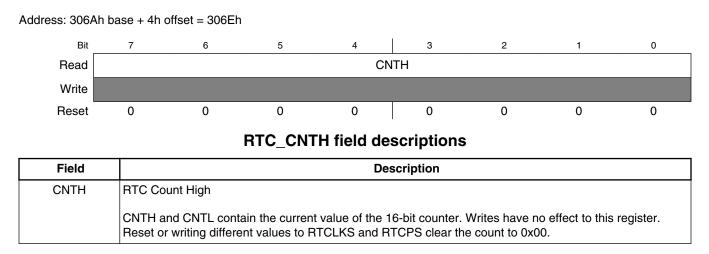

Field	Description
	RTC Modulo Low These sixteen read/write bits, MODH and MODL, contain the modulo value used to reset the count to 0x0000 upon a compare match and set the RTIF status bit. A value of 0x00 of the MODH an MODL sets the RTIF bit on each rising edge of the prescaler output. Reset sets the modulo to 0x00.

## 17.4.5 RTC Counter Register: High (RTC\_CNTH)

RTC\_CNTH, together with RTC\_CNTL, indicates the read-only value of the current RTC count of the 16-bit counter.

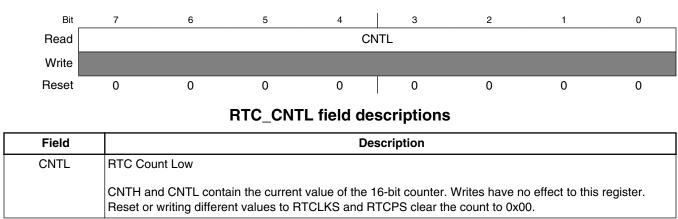

### NOTE

The RTC\_CNTL must be read first to lock the counter and then read RTC\_CNTH to correctly read 16-bit counter.

## 17.4.6 RTC Counter Register: Low (RTC\_CNTL)

RTC\_CNTL, together with RTC\_CNTH, indicates the read-only value of the current RTC count of the 16-bit counter.

Address: 306Ah base + 5h offset = 306Fh

# **17.5 Functional description**

The RTC is composed of a main 16-bit up-counter with a 16-bit modulo register, a clock source selector, and a prescaler block with binary-based and decimal-based selectable values. The module also contains software selectable interrupt logic .

After any MCU reset, the counter is stopped and reset to 0x0000, the modulus register is set to 0x0000, and the prescaler is off. The external oscillator clock is selected as the default clock source. To start the prescaler, write any value other than 0 to the Prescaler Select field (RTC\_SC2[RTCPS]).

The clock sources are software selectable: the external oscillator (OSC), on-chip low power oscillator (LPO), internal reference clock, and bus clock. The RTC Clock Select field (RTC\_SC2[RTCLKS]) is used to select the desired clock source to the prescaler dividers. If a different value is written to RTC\_SC2[RTCLKS], the prescaler and CNTH and RTC\_CNTL counters are reset to 0x00.

#### Functional description

RTC\_SC2[RTCPS] and RTC\_SC2[RTCLKS] select the desired divide-by value. If a different value is written to RTC\_SC2[RTCPS], the prescaler and RTCCNT counters are reset to 0x00. The following table shows different prescaler period values.

RTCPS	32768Hz OSC clock source prescaler period (RTCLKS = 00)	LPO clock (1 kHz) source prescaler period (RTCLKS = 01)	Internal reference clock source prescaler period (RTCLKS = 10)	Bus clock (8 MHz) source prescaler period (RTCLKS = 11)
000	Off	Off	Off	Off
001	30.5176 µs	128 ms	30.5176 µs	16 µs
010	61.0351 µs	256 ms	61.0351 µs	32 µs
011	122.0703 µs	512 ms	122.0703 µs	64 µs
100	244.1406 µs	1024 ms	244.1406 µs	128 µs
101	488.28125 µs	2048 ms	488.28125 μs	256 µs
110	976.5625 μs	100 ms	976.5625 µs	12.5 µs
111	1.9531 ms	1 s	1.9531 ms	125 µs

 Table 17-2.
 Prescaler period

The RTC Modulo register (RTC\_MODH and RTC\_MODL) allows the compare value to be set to any value from 0x0000 to 0xFFFF. When the counter is active, the counter increments at the selected rate until the count matches the modulo value. When these values match, the counter resets to 0x0000 and continues counting. The Real-Time Interrupt Flag (RTC\_SC1[RTIF]) is set whenever a match occurs. The flag sets on the transition from the modulo value to 0x0000. The modulo value written to RTC\_MODH and RTC\_MODL is latched until the RTC counter overflows or RTC\_SC2[RTCPS] is selected nonzero.

The RTC allows for an interrupt to be generated whenever RTC\_SC1[RTIF] is set. To enable the real-time interrupt, set the Real-Time Interrupt Enable field (RTC\_SC1[RTIE]). RTC\_SC1[RTIF] is cleared by writing a 1 to RTC\_SC1[RTIF].

## 17.5.1 RTC operation example

This section shows an example of the RTC operation as the counter reaches a matching value from the modulo register.

OSC (32768Hz) RTCLKS = 00b								
RTC Clock RTCPS = 01b								
RTCCNT RTCPS = 01b	32765	32766	32767	0	1	2	3	4
RTIF				' 				
16-bit modulo	32767	32767	32767	32766	32766	32766	32766	32766
				1				
RTCMOD	32766	32766	32766					
				· · · · · · · · · · · · · · · · · · ·				

Figure 17-2. RTC counter overflow example

In the above example, the external clock source is selected. The prescaler is set to RTC\_SC2[RTCPS] = 001b or passthrough. The actual modulo value used by 16-bit comparator is 32767, when the modulo value in the RTC\_MODH and RTC\_MODL registers is set to 32766. When the counter, RTC\_CNTH and RTC\_CNTL, reaches the modulo value of 32767, the counter overflows to 0x00 and continues counting. The modulo value is updated by fetching from RTC\_MODH and RTC\_MODL registers. The real-time interrupt flag, RTC\_SC1[RTIF], sets when the counter value changes from 0x7FFF to 0x0000.

## 17.6 Initialization/application information

This section provides example code to give some basic direction to a user on how to initialize and configure the RTC module. The example software is implemented in C language.

The example below shows how to implement time of day with the RTC using the OSC clock source to achieve the lowest possible power consumption.

### Example: 17.6.1 Software calendar implementation in RTC ISR

```
/* Initialize the elapsed time counters */
Seconds = 0;
Minutes = 0;
Hours = 0;
Days=0;
/* Configure RTC to interrupt every 1 second from OSC (32.768KHz) clock source */
RTC_MOD = 511; // overflow every 512 times
```

#### Initialization/application information

```
RTC_SC2 = RTC_SC2_RTCPS_MASK; // external 32768 clock selected with 1/64 predivider.
RTC_SC1 = RTC_SC1_RTIF_MASK | RTC_SC1_RTIE_MASK; // interrupt cleared and enabled
Function Name : RTC_ISR
Notes : Interrupt service routine for RTC module.
void RTC_ISR(void)
/* Clears the interrupt flag, RTIF, and interrupt request */
RTC_SC1 |= RTC_SC1_RTIF_MASK;
/* RTC interrupts every 1 Second */
Seconds++;
/* 60 seconds in a minute */
if (Seconds > 59)
Minutes++;
Seconds = 0;
}
/* 60 minutes in an hour */
if (Minutes > 59)
Hours++;
Minutes = 0;
}
/* 24 hours in a day */
if (Hours > 23)
Days ++;
Hours = 0;
```

# Chapter 18 Serial communications interface (SCI)

# 18.1 Chip specific SCI information

This device includes one independent serial communications interface (SCI) module, which can work with FTM, ACMP to realize more complicated functions, refer to System Control for more details.

The following table summarizes the external signals of SCIs modules

SCI	Functions	Default	Alternate
SCI0	TxD	PTB1/TxD	PTA3/TxD
	RxD	PTB0/RxD	PTA2/RxD

Table 18-1. SCI modules external signals

SCI0 channels can be configured on different pinouts by setting SYS\_SOPT1[SCI0PS].

# 18.2 Introduction

## 18.2.1 Features

Features of SCI module include:

- Full-duplex, standard non-return-to-zero (NRZ) format
- Double-buffered transmitter and receiver with separate enables
- Programmable baud rates (13-bit modulo divider)
- Interrupt-driven or polled operation:
  - Transmit data register empty and transmission complete
  - Receive data register full
  - Receive overrun, parity error, framing error, and noise error

#### Introduction

- Idle receiver detect
- Active edge on receive pin
- Break detect supporting LIN
- Hardware parity generation and checking
- Programmable 8-bit or 9-bit character length
- Programmable 1-bit or 2-bit stop bits
- Receiver wakeup by idle-line or address-mark
- Optional 13-bit break character generation / 11-bit break character detection
- Selectable transmitter output polarity

## 18.2.2 Modes of operation

See Section Functional description for details concerning SCI operation in these modes:

- 8- and 9-bit data modes
- Stop mode operation
- Loop mode
- Single-wire mode

# 18.2.3 Block diagram

The following figure shows the transmitter portion of the SCI.

Chapter 18 Serial communications interface (SCI)

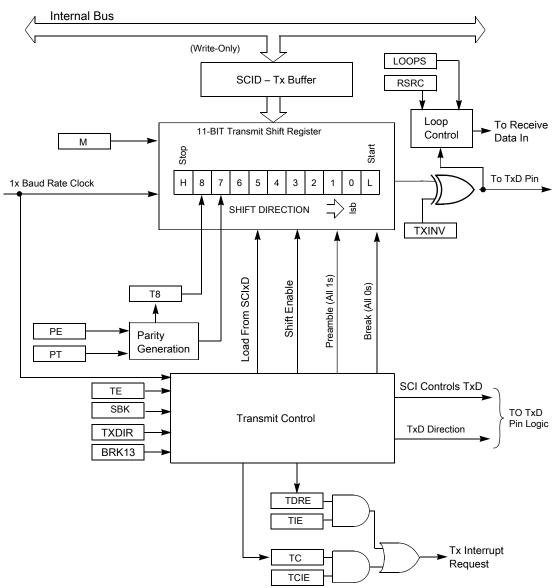

Figure 18-1. SCI transmitter block diagram

The following figure shows the receiver portion of the SCI.

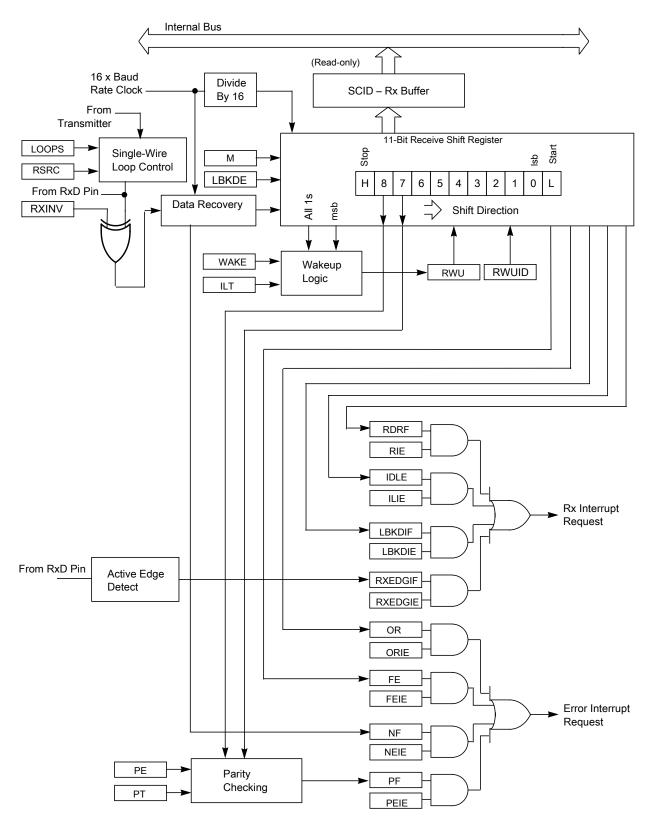

Figure 18-2. SCI receiver block diagram

# 18.3 SCI signal descriptions

The SCI signals are shown in the table found here.

Table 18-2.	SCI signal descriptions
-------------	-------------------------

Signal	Description	I/O
RxD	Receive data	I
TxD	Transmit data	I/O

## 18.3.1 Detailed signal descriptions

The detailed signal descriptions of the SCI are shown in the following table.

Signal	I/O	Description			
RxD	I	Receive data. Serial data input to receiver.			
		State meaning Whether RxD is interpreted as a 1 or 0 depends on the bit encoding method along with other configuration settings.			
		Timing Sampled at a frequency determined by the module clock divided by the baud rate.			
TxD	I/O	Transmit data. Serial data output from transmitter.			
		State meaning Whether TxD is interpreted as a 1 or 0 depends on the bit encoding method along with other configuration settings.			
		Timing	Driven at the beginning or within a bit time according to the bit encoding method along with other configuration settings. Otherwise, transmissions are independent of reception timing.		

Table 18-3. SCI—Detailed signal descriptions

# 18.4 Register definition

The SCI has 8-bit registers to control baud rate, select SCI options, report SCI status, and for transmit/receive data.

Refer to the direct-page register summary in the memory chapter of this document or the absolute address assignments for all SCI registers. This section refers to registers and control bits only by their names. An NXP-provided equate or header file is used to translate these names into the appropriate absolute addresses.

Absolute address (hex)	Register name		Access	Reset value	Section/ page
3080	SCI Baud Rate Register: High (SCI0_BDH)	8	R/W	00h	18.4.1/272
3081	SCI Baud Rate Register: Low (SCI0_BDL)	8	R/W	04h	18.4.2/273
3082	SCI Control Register 1 (SCI0_C1)	8	R/W	00h	18.4.3/273
3083	SCI Control Register 2 (SCI0_C2)	8	R/W	00h	18.4.4/275

#### SCI memory map

### 18.4.1 SCI Baud Rate Register: High (SCIx\_BDH)

This register, along with SCI\_BDL, controls the prescale divisor for SCI baud rate generation. To update the 13-bit baud rate setting [SBR12:SBR0], first write to SCI\_BDH to buffer the high half of the new value and then write to SCI\_BDL. The working value in SCI\_BDH does not change until SCI\_BDL is written.

Address: 3080h base + 0h offset = 3080h

Bit	7	6	5	4	3	2	1	0
Read Write	LBKDIE	RXEDGIE	SBNS			SBR		
Reset	0	0	0	0	0	0	0	0

#### SCIx\_BDH field descriptions

Field	Description
7	LIN Break Detect Interrupt Enable (for LBKDIF)
LBKDIE	0 Hardware interrupts from SCI_S2[LBKDIF] disabled (use polling).
	1 Hardware interrupt requested when SCI_S2[LBKDIF] flag is 1.
6 RXEDGIE	RxD Input Active Edge Interrupt Enable (for RXEDGIF)
	0 Hardware interrupts from SCI_S2[RXEDGIF] disabled (use polling).
	1 Hardware interrupt requested when SCI_S2[RXEDGIF] flag is 1.
5 SBNS	Stop Bit Number Select
	SBNS determines whether data characters are one or two stop bits.
	0 One stop bit.
	1 Two stop bit.
SBR	Baud Rate Modulo Divisor.

Table continues on the next page ...

SCIx_BDH field	descriptions	(continued)
----------------	--------------	-------------

Field	Description
	The 13 bits in SBR[12:0] are referred to collectively as BR, and they set the modulo divide rate for the SCI baud rate generator. When BR is cleared, the SCI baud rate generator is disabled to reduce supply current. When BR is 1 - 8191, the SCI baud rate equals BUSCLK/(16×BR).

### 18.4.2 SCI Baud Rate Register: Low (SCIx\_BDL)

This register, along with SCI\_BDH, control the prescale divisor for SCI baud rate generation. To update the 13-bit baud rate setting [SBR12:SBR0], first write to SCI\_BDH to buffer the high half of the new value and then write to SCI\_BDL. The working value in SCI\_BDH does not change until SCI\_BDL is written.

SCI\_BDL is reset to a non-zero value, so after reset the baud rate generator remains disabled until the first time the receiver or transmitter is enabled; that is, SCI\_C2[RE] or SCI\_C2[TE] bits are written to 1.

Address: 3080h base + 1h offset = 3081h

Bit	7	6	5	4	3	2	1	0
Read Write				SE	3R			
Reset	0	0	0	0	0	1	0	0

PE Enables hardware parity generation and checking. When parity is enabled, the most significant bit the data character, eighth or ninth data bit, is treated as the parity bit.	(msb) of
<ul><li>0 No hardware parity generation or checking.</li><li>1 Parity enabled.</li></ul>	
0 Parity Type	
PT Provided parity is enabled (PE = 1), this bit selects even or odd parity. Odd parity means the total r of 1s in the data character, including the parity bit, is odd. Even parity means the total number of 1s data character, including the parity bit, is even.	
0 Even parity.	
1 Odd parity.	

## 18.4.4 SCI Control Register 2 (SCIx\_C2)

This register can be read or written at any time.

#### Address: 3080h base + 3h offset = 3083h

Bit	7	6	5	4	3	2	1	0
Read Write	TIE	TCIE	RIE	ILIE	TE	RE	RWU	SBK
Reset	0	0	0	0	0	0	0	0

#### SCIx\_C2 field descriptions

Field	Description
7	Transmit Interrupt Enable for TDRE
TIE	0 Hardware interrupts from TDRE disabled; use polling.
	1 Hardware interrupt requested when TDRE flag is 1.
6	Transmission Complete Interrupt Enable for TC
TCIE	
	<ul> <li>Hardware interrupts from TC disabled; use polling.</li> <li>Hardware interrupt requested when TC flag is 1.</li> </ul>
5 RIE	Receiver Interrupt Enable for RDRF
	0 Hardware interrupts from RDRF disabled; use polling.
	1 Hardware interrupt requested when RDRF flag is 1.
4 ILIE	Idle Line Interrupt Enable for IDLE
	0 Hardware interrupts from IDLE disabled; use polling.
	1 Hardware interrupt requested when IDLE flag is 1.
3	Transmitter Enable
TE	TE must be 1 to use the SCI transmitter. When TE is set, the SCI forces the TxD pin to act as an output for the SCI system.
	When the SCI is configured for single-wire operation (LOOPS = RSRC = 1), TXDIR controls the direction of traffic on the single SCI communication line (TxD pin).
	TE can also queue an idle character by clearing TE then setting TE while a transmission is in progress.
	When TE is written to 0, the transmitter keeps control of the port TxD pin until any data, queued idle, or queued break character finishes transmitting before allowing the pin to revert to a general-purpose I/O pin.
	0 Transmitter off.
	1 Transmitter on.
2	Receiver Enable
RE	
	When the SCI receiver is off, the RxD pin reverts to being a general-purpose port I/O pin. If LOOPS is set the RxD pin reverts to being a general-purpose I/O pin even if RE is set.
	0 Receiver off.
	1 Receiver on.
1	Receiver Wakeup Control
RWU	

Table continues on the next page ...

Field	Description
	This bit can be written to 1 to place the SCI receiver in a standby state where it waits for automatic hardware detection of a selected wakeup condition. The wakeup condition is an idle line between messages, WAKE = 0, idle-line wakeup, or a logic 1 in the most significant data bit in a character, WAKE = 1, address-mark wakeup. Application software sets RWU and, normally, a selected hardware condition automatically clears RWU.
	0 Normal SCI receiver operation.
	1 SCI receiver in standby waiting for wakeup condition.
0 SBK	Send Break
	Writing a 1 and then a 0 to SBK queues a break character in the transmit data stream. Additional break characters of 10 or 11 or 12, 13 or 14 or 15 if BRK13 = 1, bit times of logic 0 are queued as long as SBK is set. Depending on the timing of the set and clear of SBK relative to the information currently being transmitted, a second break character may be queued before software clears SBK.
	0 Normal transmitter operation.
	1 Queue break character(s) to be sent.

### SCIx\_C2 field descriptions (continued)

## 18.4.5 SCI Status Register 1 (SCIx\_S1)

This register has eight read-only status flags. Writes have no effect. Special software sequences, which do not involve writing to this register, clear these status flags.

Address: 3080h base + 4h offset = 3084h

Bit	7	6	5	4	3	2	1	0
Read	TDRE	TC	RDRF	IDLE	OR	NF	FE	PF
Write								
Reset	1	1	0	0	0	0	0	0

#### SCIx\_S1 field descriptions

Field	Description
7	Transmit Data Register Empty Flag
TDRE	<ul> <li>TDRE is set out of reset and when a transmit data value transfers from the transmit data buffer to the transmit shifter, leaving room for a new character in the buffer. To clear TDRE, read SCI_S1 with TDRE set and then write to the SCI data register (SCI_D).</li> <li>Transmit data register (buffer) full.</li> <li>Transmit data register (buffer) empty.</li> </ul>
6	Transmission Complete Flag
TC	<ul> <li>TC is set out of reset and when TDRE is set and no data, preamble, or break character is being transmitted.</li> <li>TC is cleared automatically by reading SCI_S1 with TC set and then doing one of the following:</li> <li>Write to the SCI data register (SCI_D) to transmit new data</li> </ul>
	<ul> <li>Queue a preamble by changing TE from 0 to 1</li> <li>Queue a break character by writing 1 to SCI_C2[SBK]</li> </ul>
	Table continues on the next page

## SCIx\_S1 field descriptions (continued)

Field	Description
	0 Transmitter active (sending data, a preamble, or a break).
	1 Transmitter idle (transmission activity complete).
5 RDRF	Receive Data Register Full Flag
	RDRF becomes set when a character transfers from the receive shifter into the receive data register (SCI_D). To clear RDRF, read SCI_S1 with RDRF set and then read the SCI data register (SCI_D).
	<ol> <li>Receive data register empty.</li> <li>Receive data register full.</li> </ol>
4	Idle Line Flag
IDLE	IDLE is set when the SCI receive line becomes idle for a full character time after a period of activity. When ILT is cleared, the receiver starts counting idle bit times after the start bit. If the receive character is all 1s, these bit times and the stop bits time count toward the full character time of logic high, 10 or 11 bit times depending on the M control bit, needed for the receiver to detect an idle line. When ILT is set, the receive doesn't start counting idle bit times until after the stop bits. The stop bits and any logic high bit times at the end of the previous character do not count toward the full character time of logic high needed for the receiver to detect an idle line.
	To clear IDLE, read SCI_S1 with IDLE set and then read the SCI data register (SCI_D). After IDLE has been cleared, it cannot become set again until after a new character has been received and RDRF has been set. IDLE is set only once even if the receive line remains idle for an extended period.
	0 No idle line detected.
	1 Idle line was detected.
3 OR	Receiver Overrun Flag
on	OR is set when a new serial character is ready to be transferred to the receive data register (buffer), but the previously received character has not been read from SCI_D yet. In this case, the new character, and all associated error information, is lost because there is no room to move it into SCI_D. To clear OR, read SCI_S1 with OR set and then read the SCI data register (SCI_D).
	0 No overrun.
	1 Receive overrun (new SCI data lost).
2	Noise Flag
NF	The advanced sampling technique used in the receiver takes seven samples during the start bit and three samples in each data bit and the stop bits. If any of these samples disagrees with the rest of the samples within any bit time in the frame, the flag NF is set at the same time as RDRF is set for the character. To clear NF, read SCI_S1 and then read the SCI data register (SCI_D).
	0 No noise detected.
	<ol> <li>Noise detected.</li> <li>Noise detected in the received character in SCI_D.</li> </ol>
1	Framing Error Flag
FE	FE is set at the same time as RDRF when the receiver detects a logic 0 where the stop bits was expected. This suggests the receiver was not properly aligned to a character frame. To clear FE, read SCI_S1 with FE set and then read the SCI data register (SCI_D).
	<ul> <li>No framing error detected. This does not guarantee the framing is correct.</li> <li>Framing error.</li> </ul>

Table continues on the next page ...

Field	Description
	PF is set at the same time as RDRF when parity is enabled ( $PE = 1$ ) and the parity bit in the received character does not agree with the expected parity value. To clear PF, read SCI_S1 and then read the SCI data register (SCI_D).
	<ul><li>0 No parity error.</li><li>1 Parity error.</li></ul>

#### SCIx\_S1 field descriptions (continued)

### 18.4.6 SCI Status Register 2 (SCIx\_S2)

This register contains one read-only status flag.

When using an internal oscillator in a LIN system, it is necessary to raise the break detection threshold one bit time. Under the worst case timing conditions allowed in LIN, it is possible that a 0x00 data character can appear to be 10.26 bit times long at a slave running 14% faster than the master. This would trigger normal break detection circuitry designed to detect a 10-bit break symbol. When the LBKDE bit is set, framing errors are inhibited and the break detection threshold changes from 10 bits to 11 bits, preventing false detection of a 0x00 data character as a LIN break symbol.

Address: 3080h base + 5h offset = 3085h

Bit	7	6	5	4	3	2	1	0
Read	LBKDIF	RXEDGIF	0	RXINV	RWUID	BRK13	LBKDE	RAF
Write	LDKDIF	RAEDGIF			RWUID	DRK13	LDKDE	
Reset	0	0	0	0	0	0	0	0

#### SCIx\_S2 field descriptions

Field	Description
7	LIN Break Detect Interrupt Flag
LBKDIF	LBKDIF is set when the LIN break detect circuitry is enabled and a LIN break character is detected. LBKDIF is cleared by writing a 1 to it.
	0 No LIN break character has been detected.
	1 LIN break character has been detected.
6 RXEDGIF	RxD Pin Active Edge Interrupt Flag
	RXEDGIF is set when an active edge, falling if RXINV = 0, rising if RXINV=1, on the RxD pin occurs. RXEDGIF is cleared by writing a 1 to it.
	0 No active edge on the receive pin has occurred.
	1 An active edge on the receive pin has occurred.
5	This field is reserved.
Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

### SCIx\_S2 field descriptions (continued)

Field	Description
4	Receive Data Inversion
RXINV	Setting this bit reverses the polarity of the received data input.
	NOTE: Setting RXINV inverts the RxD input for all cases: data bits, start and stop bits, break, and idle.
	0 Receive data not inverted.
	1 Receive data inverted.
3	Receive Wake Up Idle Detect
RWUID	RWUID controls whether the idle character that wakes up the receiver sets the IDLE bit.
	0 During receive standby state (RWU = 1), the IDLE bit does not get set upon detection of an idle character.
	1 During receive standby state (RWU = 1), the IDLE bit gets set upon detection of an idle character.
2 BRK13	Break Character Generation Length
DIRTO	BRK13 selects a longer transmitted break character length. Detection of a framing error is not affected by the state of this bit.
	<ul> <li>Break character is transmitted with length of 10 bit times (if M = 0, SBNS = 0) or 11 (if M = 1, SBNS = 0 or M = 0, SBNS = 1) or 12 (if M = 1, SBNS = 1).</li> </ul>
	1 Break character is transmitted with length of 13 bit times (if $M = 0$ , SBNS = 0) or 14 (if $M = 1$ , SBNS = 0 or $M = 0$ , SBNS = 1) or 15 (if $M = 1$ , SBNS = 1).
1	LIN Break Detection Enable
LBKDE	LBKDE selects a longer break character detection length. While LBKDE is set, framing error (FE) and receive data register full (RDRF) flags are prevented from setting.
	<ul> <li>Break character is detected at length 10 bit times (if M = 0, SBNS = 0) or 11 (if M = 1, SBNS = 0 or M = 0, SBNS = 1) or 12 (if M = 1, SBNS = 1).</li> </ul>
	<ul> <li>Break character is detected at length of 11 bit times (if M = 0, SBNS = 0) or 12 (if M = 1, SBNS = 0 or M = 0, SBNS = 1) or 13 (if M = 1, SBNS = 1).</li> </ul>
0	Receiver Active Flag
RAF	RAF is set when the SCI receiver detects the beginning of a valid start bit, and RAF is cleared automatically when the receiver detects an idle line. This status flag can be used to check whether an SCI character is being received before instructing the MCU to go to stop mode.
	0 SCI receiver idle waiting for a start bit.
	1 SCI receiver active (RxD input not idle).

## 18.4.7 SCI Control Register 3 (SCIx\_C3)

Address: 3080h base + 6h offset = 3086h

Bit	7	6	5	4	3	2	1	0
Read	R8	Т8	TXDIR	TXINV	ORIE	NEIE	FEIE	PEIE
Write		10	TADIN		ONIL			
Reset	0	0	0	0	0	0	0	0

### SCIx\_C3 field descriptions

Field	Description
7	Ninth Data Bit for Receiver
R8	When the SCI is configured for 9-bit data ( $M = 1$ ), R8 can be thought of as a ninth receive data bit to the left of the msb of the buffered data in the SCI_D register. When reading 9-bit data, read R8 before reading SCI_D because reading SCI_D completes automatic flag clearing sequences that could allow R8 and SCI_D to be overwritten with new data.
6	Ninth Data Bit for Transmitter
T8	When the SCI is configured for 9-bit data ( $M = 1$ ), T8 may be thought of as a ninth transmit data bit to the left of the msb of the data in the SCI_D register. When writing 9-bit data, the entire 9-bit value is transferred to the SCI shift register after SCI_D is written so T8 should be written, if it needs to change from its previous value, before SCI_D is written. If T8 does not need to change in the new value, such as when it is used to generate mark or space parity, it need not be written each time SCI_D is written.
5	TxD Pin Direction in Single-Wire Mode
TXDIR	When the SCI is configured for single-wire half-duplex operation (LOOPS = $RSRC = 1$ ), this bit determines the direction of data at the TxD pin.
	0 TxD pin is an input in single-wire mode.
	1 TxD pin is an output in single-wire mode.
4 TXINV	Transmit Data Inversion
	Setting this bit reverses the polarity of the transmitted data output.
	<b>NOTE:</b> Setting TXINV inverts the TxD output for all cases: data bits, start and stop bits, break, and idle.
	0 Transmit data not inverted.
	1 Transmit data inverted.
3 ORIE	Overrun Interrupt Enable
	This bit enables the overrun flag (OR) to generate hardware interrupt requests.
	0 OR interrupts disabled; use polling.
	1 Hardware interrupt requested when OR is set.
2 NEIE	Noise Error Interrupt Enable
	This bit enables the noise flag (NF) to generate hardware interrupt requests.
	0 NF interrupts disabled; use polling).
	1 Hardware interrupt requested when NF is set.
1 FEIE	Framing Error Interrupt Enable
	This bit enables the framing error flag (FE) to generate hardware interrupt requests.
	0 FE interrupts disabled; use polling).
	1 Hardware interrupt requested when FE is set.
0 PEIE	Parity Error Interrupt Enable
	This bit enables the parity error flag (PF) to generate hardware interrupt requests.
	0 PF interrupts disabled; use polling).
	1 Hardware interrupt requested when PF is set.

## 18.4.8 SCI Data Register (SCIx\_D)

This register is actually two separate registers. Reads return the contents of the read-only receive data buffer and writes go to the write-only transmit data buffer. Reads and writes of this register are also involved in the automatic flag clearing mechanisms for the SCI status flags.

Address: 3080h base + 7h offset = 3087h

Bit	7	6	5	4	3	2	1	0
Read Write	R7T7	R6T6	R5T5	R4T4	R3T3	R2T2	R1T1	R0T0
Reset	0	0	0	0	0	0	0	0

Field	Description
7 R7T7	Read receive data buffer 7 or write transmit data buffer 7.
6 R6T6	Read receive data buffer 6 or write transmit data buffer 6.
5 R5T5	Read receive data buffer 5 or write transmit data buffer 5.
4 R4T4	Read receive data buffer 4 or write transmit data buffer 4.
3 R3T3	Read receive data buffer 3 or write transmit data buffer 3.
2 R2T2	Read receive data buffer 2 or write transmit data buffer 2.
1 R1T1	Read receive data buffer 1 or write transmit data buffer 1.
0 R0T0	Read receive data buffer 0 or write transmit data buffer 0.

#### SCIx\_D field descriptions

## **18.5 Functional description**

The SCI allows full-duplex, asynchronous, NRZ serial communication among the MCU and remote devices, including other MCUs.

The SCI comprises a baud rate generator, transmitter, and receiver block. The transmitter and receiver operate independently, although they use the same baud rate generator. During normal operation, the MCU monitors the status of the SCI, writes the data to be transmitted, and processes received data. The following describes each of the blocks of the SCI.

# 18.5.1 Baud rate generation

As shown in the figure found here, the clock source for the SCI baud rate generator is the bus-rate clock.

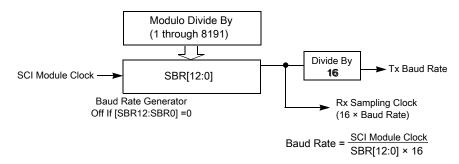

Figure 18-3. SCI baud rate generation

SCI communications require the transmitter and receiver, which typically derive baud rates from independent clock sources, to use the same baud rate. Allowed tolerance on this baud frequency depends on the details of how the receiver synchronizes to the leading edge of the start bit and how bit sampling is performed.

The MCU resynchronizes to bit boundaries on every high-to-low transition. In the worst case, there are no such transitions in the full 10- or 11-bit or 12-bittime character frame so any mismatch in baud rate is accumulated for the whole character time. For an NXP SCI system whose bus frequency is driven by a crystal, the allowed baud rate mismatch is about  $\pm 4.5$  percent for 8-bit data format and about  $\pm 4$  percent for 9-bit data format. Although baud rate modulo divider settings do not always produce baud rates that exactly match standard rates, it is normally possible to get within a few percent, which is acceptable for reliable communications.

# 18.5.2 Transmitter functional description

This section describes the overall block diagram for the SCI transmitter, as well as specialized functions for sending break and idle characters.

The transmitter output (TxD) idle state defaults to logic high, SCI\_C3[TXINV] is cleared following reset. The transmitter output is inverted by setting SCI\_C3[TXINV]. The transmitter is enabled by setting the TE bit in SCI\_C2. This queues a preamble character that is one full character frame of the idle state. The transmitter then remains idle until data is available in the transmit data buffer. Programs store data into the transmit data buffer by writing to the SCI data register (SCI\_D).

The central element of the SCI transmitter is the transmit shift register that is 10 or 11 or 12 bits long depending on the setting in the SCI\_C1[M] control bit and SCI\_BDH[SBNS] bit. For the remainder of this section, assume SCI\_C1[M] is cleared, SCI\_BDH[SBNS] is also cleared, selecting the normal 8-bit data mode. In 8-bit data mode, the shift register holds a start bit, eight data bits, and a stop bit. When the transmit shift register is available for a new SCI character, the value waiting in the transmit data register is transferred to the shift register, synchronized with the baud rate clock, and the transmit data register empty (SCI\_S1[TDRE]) status flag is set to indicate another character may be written to the transmit data buffer at SCI\_D.

### NOTE

Always read SCI\_S1 before writing to SCI\_D to allow data to be transmitted.

If no new character is waiting in the transmit data buffer after a stop bit is shifted out the TxD pin, the transmitter sets the transmit complete flag and enters an idle mode, with TxD high, waiting for more characters to transmit.

Writing 0 to SCI\_C2[TE] does not immediately release the pin to be a general-purpose I/O pin. Any transmit activity in progress must first be completed. This includes data characters in progress, queued idle characters, and queued break characters.

## 18.5.2.1 Send break and queued idle

SCI\_C2[SBK] sends break characters originally used to gain the attention of old teletype receivers. Break characters are a full character time of logic 0, 10 bit times including the start and stop bits. A longer break of 13 bit times can be enabled by setting SCI\_S2[BRK13]. Normally, a program would wait for SCI\_S1[TDRE] to become set to indicate the last character of a message has moved to the transmit shifter, write 1, and then write 0 to SCI\_C2[SBK]. This action queues a break character to be sent as soon as the shifter is available. If SCI\_C2[SBK] remains 1 when the queued break moves into the shifter, synchronized to the baud rate clock, an additional break character is queued. If the receiving device is another NXP SCI, the break characters are received as 0s in all eight data bits and a framing error (SCI\_S1[FE] = 1) occurs.

#### Functional description

When idle-line wake-up is used, a full character time of idle (logic 1) is needed between messages to wake up any sleeping receivers. Normally, a program would wait for SCI\_S1[TDRE] to become set to indicate the last character of a message has moved to the transmit shifter, then write 0 and then write 1 to the SCI\_C2[TE] bit. This action queues an idle character to be sent as soon as the shifter is available. As long as the character in the shifter does not finish while SCI\_C2[TE] is cleared, the SCI transmitter never actually releases control of the TxD pin. If there is a possibility of the shifter finishing while SCI\_C2[TE] is cleared, set the general-purpose I/O controls so the pin shared with TxD is an output driving a logic 1. This ensures that the TxD line looks like a normal idle line even if the SCI loses control of the port pin between writing 0 and then 1 to SCI\_C2[TE].

The length of the break character is affected by the SCI\_S2[BRK13] and SCI\_C1[M] as shown below.

BRK13	м	SBNS	Break character length
0	0	0	10 bit times
0	0	1	11 bit times
0	1	0	11 bit times
0	1	1	12 bit times
1	0	0	13 bit times
1	0	1	14 bit times
1	1	0	14 bit times
1	1	1	15 bit times

Table 18-4. Break character length

# 18.5.3 Receiver functional description

In this section, the receiver block diagram is a guide for the overall receiver functional description.

Next, the data sampling technique used to reconstruct receiver data is described in more detail. Finally, two variations of the receiver wakeup function are explained.

The receiver input is inverted by setting SCI\_S2[RXINV]. The receiver is enabled by setting the SCI\_C2[RE] bit. Character frames consist of a start bit of logic 0, eight (or nine) data bits (lsb first), and one (or two) stop bits of logic 1. For information about 9-bit data mode, refer to 8- and 9-bit data modes. For the remainder of this discussion, assume the SCI is configured for normal 8-bit data mode.

After receiving the stop bit into the receive shifter, and provided the receive data register is not already full, the data character is transferred to the receive data register and the receive data register full (SCI\_S1[RDRF]) status flag is set. If SCI\_S1[RDRF] was already set indicating the receive data register (buffer) was already full, the overrun (OR) status flag is set and the new data is lost. Because the SCI receiver is double-buffered, the program has one full character time after SCI\_S1[RDRF] is set before the data in the receive data buffer must be read to avoid a receiver overrun.

When a program detects that the receive data register is full (SCI\_S1[RDRF] = 1), it gets the data from the receive data register by reading SCI\_D. The SCI\_S1[RDRF] flag is cleared automatically by a two-step sequence normally satisfied in the course of the user's program that manages receive data. Refer to Interrupts and status flags for more details about flag clearing.

## 18.5.3.1 Data sampling technique

The SCI receiver uses a 16× baud rate clock for sampling. The oversampling ratio is fixed at 16. The receiver starts by taking logic level samples at 16 times the baud rate to search for a falling edge on the RxD serial data input pin. A falling edge is defined as a logic 0 sample after three consecutive logic 1 samples. The 16× baud rate clock divides the bit time into 16 segments labeled SCI\_D[RT1] through SCI\_D[RT16]. When a falling edge is located, three more samples are taken at SCI\_D[RT3], SCI\_D[RT5], and SCI\_D[RT7] to make sure this was a real start bit and not merely noise. If at least two of these three samples are 0, the receiver assumes it is synchronized to a receive character.

The receiver then samples each bit time, including the start and stop bits, at SCI\_D[RT8], SCI\_D[RT9], and SCI\_D[RT10] to determine the logic level for that bit. The logic level is interpreted to be that of the majority of the samples taken during the bit time. In the case of the start bit, the bit is assumed to be 0 if at least two of the samples at SCI\_D[RT3], SCI\_D[RT5], and SCI\_D[RT7] are 0 even if one or all of the samples taken at SCI\_D[RT8], SCI\_D[RT9], and SCI\_D[RT9] are 1s. If any sample in any bit time, including the start and stop bits, in a character frame fails to agree with the logic level for that bit, the noise flag (SCI\_S1[NF]) is set when the received character is transferred to the receive data buffer.

The falling edge detection logic continuously looks for falling edges. If an edge is detected, the sample clock is resynchronized to bit times. This improves the reliability of the receiver in the presence of noise or mismatched baud rates. It does not improve worst case analysis because some characters do not have any extra falling edges anywhere in the character frame.

#### Functional description

In the case of a framing error, provided the received character was not a break character, the sampling logic that searches for a falling edge is filled with three logic 1 samples so that a new start bit can be detected almost immediately.

In the case of a framing error, the receiver is inhibited from receiving any new characters until the framing error flag is cleared. The receive shift register continues to function, but a complete character cannot transfer to the receive data buffer if SCI\_S1[FE] remains set.

### 18.5.3.2 Receiver wake-up operation

Receiver wake-up is a hardware mechanism that allows an SCI receiver to ignore the characters in a message intended for a different SCI receiver. In such a system, all receivers evaluate the first character(s) of each message, and as soon as they determine the message is intended for a different receiver, they write logic 1 to the receiver wake up control field (SCI\_C2[RWU]). When SCI\_C2[RWU] is set, the status flags associated with the receiver, (with the exception of the idle bit, IDLE, when SCI\_S2[RWUID] is set), are inhibited from setting, thus eliminating the software overhead for handling the unimportant message characters. At the end of a message, or at the beginning of the next message, all receivers automatically force SCI\_C2[RWU] to 0, so all receivers wake up in time to look at the first character(s) of the next message.

### 18.5.3.2.1 Idle-line wakeup

When wake is cleared, the receiver is configured for idle-line wakeup. In this mode, SCI\_C2[RWU] is cleared automatically when the receiver detects a full character time of the idle-line level. The SCI\_C1[M] control field selects 8-bit or 9-bit data mode and SCI\_BDH[SBNS] selects 1-bit or 2-bit stop bit number that determines how many bit times of idle are needed to constitute a full character time, 10 or 11 or 12 bit times because of the start and stop bits.

When SCII\_C2[RWU] is 1 and SCI\_S2[RWUID] is 0, the idle condition that wakes up the receiver does not set SCI\_S1[IDLE]. The receiver wakes up and waits for the first data character of the next message that sets SCI\_S1[RDRF] and generates an interrupt, if enabled. When SCI\_S2[RWUID] is 1, any idle condition sets SCI\_S1[IDLE] flag and generates an interrupt if enabled, regardless of whether SCI\_C2[RWU] is 0 or 1.

The idle-line type (SCI\_C1[ILT]) control bit selects one of two ways to detect an idle line. When SCI\_C1[ILT] is cleared, the idle bit counter starts after the start bit so the stop bit and any logic 1s at the end of a character count toward the full character time of idle. When SCI\_C1[ILT] is set, the idle bit counter does not start until after a stop bit time, so the idle detection is not affected by the data in the last character of the previous message.

### 18.5.3.2.2 Address-mark wakeup

When wake is set, the receiver is configured for address-mark wakeup. In this mode, SCI\_C2[RWU] is cleared automatically when the receiver detects a, or two, if SCI\_BDH[SBNS] = 1, logic 1 in the most significant bits of a received character, eighth bit when SCI\_C1[M] is cleared and ninth bit when SCI\_C1[M] is set.

Address-mark wakeup allows messages to contain idle characters, but requires the msb be reserved for use in address frames. The one, or two, if  $SCI_BDH[SBNS] = 1$ , logic 1s msb of an address frame clears the  $SCI_C2[RWU]$  bit before the stop bits are received and sets the  $SCI_S1[RDRF]$  flag. In this case, the character with the msb set is received even though the receiver was sleeping during most of this character time.

# 18.5.4 Interrupts and status flags

The SCI system has three separate interrupt vectors to reduce the amount of software needed to isolate the cause of the interrupt.

One interrupt vector is associated with the transmitter for SCI\_S1[TDRE] and SCI\_S1[TC] events. Another interrupt vector is associated with the receiver for RDRF, IDLE, RXEDGIF, and LBKDIF events. A third vector is used for OR, NF, FE, and PF error conditions. Each of these ten interrupt sources can be separately masked by local interrupt enable masks. The flags can be polled by software when the local masks are cleared to disable generation of hardware interrupt requests.

The SCI transmitter has two status flags that can optionally generate hardware interrupt requests. Transmit data register empty (SCI\_S1[TDRE]) indicates when there is room in the transmit data buffer to write another transmit character to SCI\_D. If the transmit interrupt enable (SCI\_C2[TIE]) bit is set, a hardware interrupt is requested when SCI\_S1[TDRE] is set. Transmit complete (SCI\_S1[TC]) indicates that the transmitter is finished transmitting all data, preamble, and break characters and is idle with TxD at the inactive level. This flag is often used in systems with modems to determine when it is safe to turn off the modem. If the transmit complete interrupt enable (SCI\_C2[TCIE]) bit is set, a hardware interrupt is requested when SCI\_S1[TDRE] and SCI\_S1[TC] status flags if the corresponding SCI\_C2[TIE] or SCI\_C2[TCIE] local interrupt masks are cleared.

When a program detects that the receive data register is full (SCI\_S1[RDRF] = 1), it gets the data from the receive data register by reading SCI\_D. The SCI\_S1[RDRF] flag is cleared by reading SCI\_S1 while SCI\_S1[RDRF] is set and then reading SCI\_D.

#### Functional description

When polling is used, this sequence is naturally satisfied in the normal course of the user program. If hardware interrupts are used, SCI\_S1 must be read in the interrupt service routine (ISR). Normally, this is done in the ISR anyway to check for receive errors, so the sequence is automatically satisfied.

The IDLE status flag includes logic that prevents it from getting set repeatedly when the RxD line remains idle for an extended period of time. IDLE is cleared by reading SCI\_S1 while SCI\_S1[IDLE] is set and then reading SCI\_D. After SCI\_S1[IDLE] has been cleared, it cannot become set again until the receiver has received at least one new character and has set SCI\_S1[RDRF].

If the associated error was detected in the received character that caused SCI\_S1[RDRF] to be set, the error flags - noise flag (SCI\_S1[NF]), framing error (SCI\_S1[FE]), and parity error flag (SCI\_S1[PF]) - are set at the same time as SCI\_S1[RDRF]. These flags are not set in overrun cases.

If SCI\_S1[RDRF] was already set when a new character is ready to be transferred from the receive shifter to the receive data buffer, the overrun (SCI\_S1[OR]) flag is set instead of the data along with any associated NF, FE, or PF condition is lost.

At any time, an active edge on the RxD serial data input pin causes the  $SCI_S2[RXEDGIF]$  flag to set. The  $SCI_S2[RXEDGIF]$  flag is cleared by writing a 1 to it. This function depends on the receiver being enabled ( $SCI_C2[RE] = 1$ ).

### 18.5.5 Baud rate tolerance

A transmitting device may operate at a baud rate below or above that of the receiver.

Accumulated bit time misalignment can cause one of the three stop bit data samples (RT8, RT9, and RT10) to fall outside the actual stop bit. A noise error will occur if the RT8, RT9, and RT10 samples are not all the same logical values. A framing error will occur if the receiver clock is misaligned in such a way that the majority of the RT8, RT9, and RT10 stop bit samples are a logic zero.

As the receiver samples an incoming frame, it re-synchronizes the RT clock on any valid falling edge within the frame. Resynchronization within frames will correct a misalignment between transmitter bit times and receiver bit times.

## 18.5.5.1 Slow data tolerance

Figure 18-4 shows how much a slow received frame can be misaligned without causing a noise error or a framing error. The slow stop bit begins at RT8 instead of RT1 but arrives in time for the stop bit data samples at RT8, RT9, and RT10.

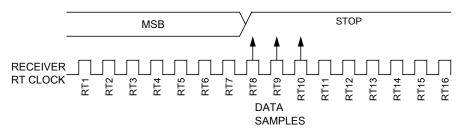

Figure 18-4. Slow data

For an 8-bit data and 1 stop bit character, data sampling of the stop bit takes the receiver 9 bit times x 16 RT cycles +10 RT cycles =154 RT cycles.

With the misaligned character shown in Figure 18-4, the receiver counts 154 RT cycles at the point when the count of the transmitting device is 9 bit times x 16 RT cycles + 3 RT cycles = 147 RT cycles.

The maximum percent difference between the receiver count and the transmitter count of a slow 8-bit data and 1 stop bit character with no errors is:

 $((154 - 147) / 154) \ge 100 = 4.54\%$ 

For a 9-bit data or 2 stop bits character, data sampling of the stop bit takes the receiver 10 bit times x 16 RT cycles + 10 RT cycles = 170 RT cycles.

With the misaligned character shown in Figure 18-4, the receiver counts 170 RT cycles at the point when the count of the transmitting device is 10 bit times x 16 RT cycles + 3 RT cycles = 163 RT cycles.

The maximum percent difference between the receiver count and the transmitter count of a slow 9-bit or 2 stop bits character with no errors is:

 $((170 - 163) / 170) \ge 100 = 4.12\%$ 

For a 9-bit data and 2 stop bit character, data sampling of the stop bit takes the receiver 11 bit times x 16 RT cycles + 10 RT cycles = 186 RT cycles.

With the misaligned character shown in Figure 18-4, the receiver counts 186 RT cycles at the point when the count of the transmitting device is 11 bit times x 16 RT cycles + 3 RT cycles = 179 RT cycles.

The maximum percent difference between the receiver count and the transmitter count of a slow 9-bit and 2 stop bits character with no errors is:  $((186 - 179) / 186) \times 100 = 3.76\%$ 

## 18.5.5.2 Fast data tolerance

Figure 18-5 shows how much a fast received frame can be misaligned. The fast stop bit ends at RT10 instead of RT16 but is still sampled at RT8, RT9, and RT10.

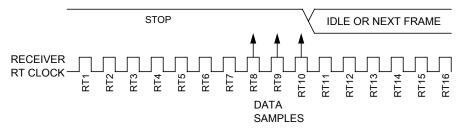

Figure 18-5. Fast data

For an 8-bit data and 1 stop bit character, data sampling of the stop bit takes the receiver 9 bit times x 16 RT cycles + 10 RT cycles = 154 RT cycles.

With the misaligned character shown in Figure 18-5, the receiver counts 154 RT cycles at the point when the count of the transmitting device is 10 bit times x 16 RT cycles = 160 RT cycles.

The maximum percent difference between the receiver count and the transmitter count of a fast 8-bit and 1 stop bit character with no errors is:

 $((154 - 160) / 154) \ge 100 = 3.90\%$ 

For a 9-bit data or 2 stop bits character, data sampling of the stop bit takes the receiver 10 bit times x 16 RT cycles + 10 RT cycles = 170 RT cycles.

With the misaligned character shown in, the receiver counts 170 RT cycles at the point when the count of the transmitting device is 11 bit times x 16 RT cycles = 176 RT cycles.

The maximum percent difference between the receiver count and the transmitter count of a fast 9-bit or 2 stop bits character with no errors is:

 $((170 - 176) / 170) \ge 100 = 3.53\%$ 

For a 9-bit data and 2 stop bits character, data sampling of the stop bit takes the receiver 11 bit times x 16 RT cycles + 10 RT cycles = 186 RT cycles.

With the misaligned character shown in, the receiver counts 186 RT cycles at the point when the count of the transmitting device is 12 bit times x 16 RT cycles = 192 RT cycles.

The maximum percent difference between the receiver count and the transmitter count of a fast 9-bit and 2 stop bits character with no errors is:

((186 - 192) / 186) x 100 = 3.23%

# 18.5.6 Additional SCI functions

The following sections describe additional SCI functions.

## 18.5.6.1 8- and 9-bit data modes

The SCI system, transmitter and receiver, can be configured to operate in 9-bit data mode by setting SCI\_C1[M]. In 9-bit mode, there is a ninth data bit to the left of the most significant bit of the SCI data register. For the transmit data buffer, this bit is stored in T8 in SCI\_C3. For the receiver, the ninth bit is held in SCI\_C3[R8].

For coherent writes to the transmit data buffer, write to SCI\_C3[T8] before writing to SCI\_D.

If the bit value to be transmitted as the ninth bit of a new character is the same as for the previous character, it is not necessary to write to SCI\_C3[T8] again. When data is transferred from the transmit data buffer to the transmit shifter, the value in SCI\_C3[T8] is copied at the same time data is transferred from SCI\_D to the shifter.

The 9-bit data mode is typically used with parity to allow eight bits of data plus the parity in the ninth bit, or it is used with address-mark wake-up so the ninth data bit can serve as the wakeup bit. In custom protocols, the ninth bit can also serve as a software-controlled marker.

## 18.5.6.2 Stop mode operation

During all stop modes, clocks to the SCI module are halted.

No SCI module registers are affected in Stop mode.

The receive input active edge detect circuit remains active in Stop mode. An active edge on the receive input brings the CPU out of Stop mode if the interrupt is not masked (SCI\_BDH[RXEDGIE] = 1).

Because the clocks are halted, the SCI module resumes operation upon exit from stop, only in Stop mode. Software must ensure stop mode is not entered while there is a character (including preamble, break and normal data) being transmitted out of or received into the SCI module, that means  $SCI_S1[TC] = 1$ ,  $SCI_S1[TDRE] = 1$ , and  $SCI_S2[RAF] = 0$  must all meet before entering stop mode.

## 18.5.6.3 Loop mode

When SCI\_C1[LOOPS] is set, the SCI\_C1[RSRC] bit in the same register chooses between loop mode (SCI\_C1[RSRC] = 0) or single-wire mode (SCI\_C1[RSRC] = 1). Loop mode is sometimes used to check software, independent of connections in the external system, to help isolate system problems. In this mode, the internal loop back connection from the transmitter to the receiver causes the receiver to receive characters that are sent out by the transmitter.

## 18.5.6.4 Single-wire operation

When SCI\_C1[LOOPS] is set, SCI\_C1[RSRC] chooses between loop mode  $(SCI_C1[RSRC] = 0)$  or single-wire mode  $(SCI_C1[RSRC] = 1)$ . Single-wire mode implements a half-duplex serial connection. The receiver is internally connected to the transmitter output and to the TxD pin. The RxD pin is not used and reverts to a general-purpose port I/O pin.

In single-wire mode, the SCI\_C3[TXDIR] bit controls the direction of serial data on the TxD pin. When SCI\_C3[TXDIR] is cleared, the TxD pin is an input to the SCI receiver and the transmitter is temporarily disconnected from the TxD pin so an external device can send serial data to the receiver. When SCI\_C3[TXDIR] is set, the TxD pin is an output driven by the transmitter. In single-wire mode, the transmitter output is internally connected to the receiver input and the RxD pin is not used by the SCI, so it reverts to a general-purpose port I/O pin.

# Chapter 19 Inter-Integrated Circuit (I2C)

# 19.1 Chip specific I2C information

This device contains an inter-integrated circuit (I2C) module.

The following table summarizes the external signals of I2C module:

S

Functions	Default	Alternate 0	Alternate 1
SCL	PTA3/SCL	PTB7/SCL	PTB3/SCL
SDA	PTA2/SDA	PTB6/SDA	PTB2/SDA

I2C channels can be reconfigured on different pinout by setting SYS\_SOPT1[IICPS].

# 19.2 Introduction

## NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The inter-integrated circuit (I<sup>2</sup>C, I2C, or IIC) module provides a method of communication between a number of devices.

The interface is designed to operate up to at least 400 kbit/s with maximum bus loading and timing. The I2C device is capable of operating at higher baud rates, up to a maximum of clock/20, with reduced bus loading. The maximum communication length and the number of devices that can be connected are limited by a maximum bus capacitance of 400 pF. The I2C module also complies with the *System Management Bus (SMBus) Specification, version 2.* 

## 19.2.1 Features

The I2C module has the following features:

- Compatible with *The I<sup>2</sup>C-Bus Specification*
- Multimaster operation
- Software programmable for one of 64 different serial clock frequencies
- Software-selectable acknowledge bit
- Interrupt-driven byte-by-byte data transfer
- Arbitration-lost interrupt with automatic mode switching from master to slave
- Calling address identification interrupt
- START and STOP signal generation and detection
- Repeated START signal generation and detection
- Acknowledge bit generation and detection
- Bus busy detection
- General call recognition
- 10-bit address extension
- Support for System Management Bus (SMBus) Specification, version 2
- Programmable input glitch filter
- Low power mode wakeup on slave address match
- Range slave address support

# 19.2.2 Modes of operation

The I2C module's operation in various low power modes is as follows:

- Run mode: This is the basic mode of operation. To conserve power in this mode, disable the module.
- Wait mode: The module continues to operate when the core is in Wait mode and can provide a wakeup interrupt.
- Stop mode: The module is inactive in Stop3 mode for reduced power consumption, except that address matching is enabled in Stop3 mode. The STOP instruction does not affect the I2C module's register states.

# 19.2.3 Block diagram

The following figure is a functional block diagram of the I2C module.

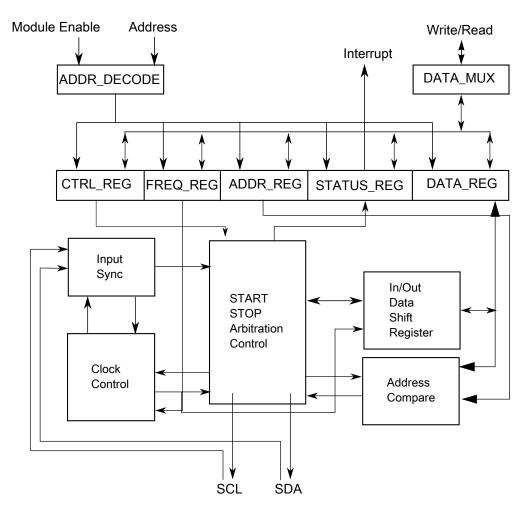

Figure 19-1. I2C Functional block diagram

# 19.3 I<sup>2</sup>C signal descriptions

The signal properties of  $I^2C$  are shown in the table found here.

Table 19-2.	I <sup>2</sup> C signal	descriptions
-------------	-------------------------	--------------

Signal	Description	I/O
SCL	Bidirectional serial clock line of the I <sup>2</sup> C system.	I/O
SDA	Bidirectional serial data line of the I <sup>2</sup> C system.	I/O

# 19.4 Memory map/register definition

This section describes in detail all I2C registers accessible to the end user.

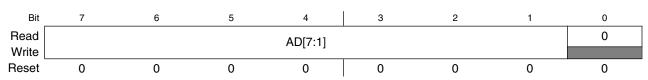

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
3070	I2C Address Register 1 (I2C_A1)	8	R/W	00h	19.4.1/296
3071	I2C Frequency Divider register (I2C_F)	8	R/W	00h	19.4.2/297
3072	I2C Control Register 1 (I2C_C1)	8	R/W	00h	19.4.3/298
3073	I2C Status register (I2C_S)	8	R/W	80h	19.4.4/299
3074	I2C Data I/O register (I2C_D)	8	R/W	00h	19.4.5/301
3075	I2C Control Register 2 (I2C_C2)	8	R/W	00h	19.4.6/302
3076	I2C Programmable Input Glitch Filter Register (I2C_FLT)	8	R/W	00h	19.4.7/303
3077	I2C Range Address register (I2C_RA)	8	R/W	00h	19.4.8/304
3078	I2C SMBus Control and Status register (I2C_SMB)	8	R/W	00h	19.4.9/305
3079	I2C Address Register 2 (I2C_A2)	8	R/W	C2h	19.4.10/306
307A	I2C SCL Low Timeout Register High (I2C_SLTH)	8	R/W	00h	19.4.11/307
307B	I2C SCL Low Timeout Register Low (I2C_SLTL)	8	R/W	00h	19.4.12/307

### I2C memory map

## 19.4.1 I2C Address Register 1 (I2C\_A1)

This register contains the slave address to be used by the I2C module.

Address: 3070h base + 0h offset = 3070h

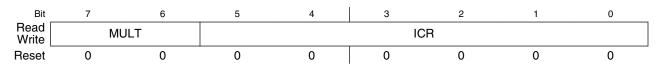

### I2C\_A1 field descriptions

Field	Description
7–1 AD[7:1]	Address Contains the primary slave address used by the I2C module when it is addressed as a slave. This field is used in the 7-bit address scheme and the lower seven bits in the 10-bit address scheme.
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

## 19.4.2 I2C Frequency Divider register (I2C\_F)

Address: 3070h base + 1h offset = 3071h

### I2C\_F field descriptions

Field			Description			
7–6 MULT	Multiplier Factor Defines the multiplier factor (mul). This factor is used along with the SCL divider to generate the I2C rate.					
	00 mul = 1

## 19.4.3 I2C Control Register 1 (I2C\_C1)

Address: 3070h base + 2h offset = 3072h

Bit	7	6	5	4	3	2	1	0
Read	IICEN	IICIE	MST	тх	ТХАК	0	WUEN	0
Write	IICEN		IVIO I		IAA	RSTA	WOEN	
Reset	0	0	0	0	0	0	0	0

### I2C\_C1 field descriptions

Field	Description
7 IICEN	I2C Enable
	Enables I2C module operation.
	0 Disabled
	1 Enabled
6 IICIE	I2C Interrupt Enable
	Enables I2C interrupt requests.
	0 Disabled
	1 Enabled
5	Master Mode Select
MST	When MST is changed from 0 to 1, a START signal is generated on the bus and master mode is selected. When this bit changes from 1 to 0, a STOP signal is generated and the mode of operation changes from master to slave.
	0 Slave mode
	1 Master mode
4 TX	Transmit Mode Select
	Selects the direction of master and slave transfers. In master mode this bit must be set according to the type of transfer required. Therefore, for address cycles, this bit is always set. When addressed as a slave this bit must be set by software according to the SRW bit in the status register.
	0 Receive
	1 Transmit

Table continues on the next page...

Field	Description
З	<ul> <li>Transmit Acknowledge Enable</li> <li>Specifies the value driven onto the SDA during data acknowledge cycles for both master and slave receivers. The value of SMB[FACK] affects NACK/ACK generation.</li> <li><b>NOTE:</b> SCL is held low until TXAK is written.</li> <li>0 An acknowledge signal is sent to the bus on the following receiving byte (if FACK is cleared) or the current receiving byte (if FACK is set).</li> <li>1 No acknowledge signal is sent to the bus on the following receiving data byte (if FACK is cleared) or</li> </ul>
	1 No acknowledge signal is sent to the bus on the following receiving data byte (if FACK is cleared) or the current receiving data byte (if FACK is set).
2 RSTA	Repeat START Writing 1 to this bit generates a repeated START condition provided it is the current master. This bit will always be read as 0. Attempting a repeat at the wrong time results in loss of arbitration.
1 WUEN	<ul> <li>Wakeup Enable</li> <li>The I2C module can wake the MCU from low power mode with no peripheral bus running when slave address matching occurs.</li> <li>0 Normal operation. No interrupt generated when address matching in low power mode.</li> <li>1 Enables the wakeup function in low power mode.</li> </ul>
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

### I2C\_C1 field descriptions (continued)

# 19.4.4 I2C Status register (I2C\_S)

Address: 3070h base + 3h offset = 3073h

Bit	7	6	5	4	3	2	1	0
Read	TCF	IAAS	BUSY	ARBL	RAM	SRW	IICIF	RXAK
Write				w1c			w1c	
Reset	1	0	0	0	0	0	0	0

### I2C\_S field descriptions

Field	Description
7 TCF	Transfer Complete Flag
	Acknowledges a byte transfer; TCF is set on the completion of a byte transfer. This bit is valid only during or immediately following a transfer to or from the I2C module. TCF is cleared by reading the I2C data register in receive mode or by writing to the I2C data register in transmit mode.
	<ul><li>0 Transfer in progress</li><li>1 Transfer complete</li></ul>
6 IAAS	Addressed As A Slave
	This bit is set by one of the following conditions:

Table continues on the next page ...

Field	Description							
	<ul> <li>The calling address matches the programmed primary slave address in the A1 register, or matches the range address in the RA register (which must be set to a nonzero value and under the condition I2C_C2[RMEN] = 1).</li> <li>C2[GCAEN] is set and a general call is received.</li> <li>SMB[SIICAEN] is set and the calling address matches the second programmed slave address.</li> <li>ALERTEN is set and an SMBus alert response address is received</li> <li>RMEN is set and an address is received that is within the range between the values of the A1 and RA registers.</li> </ul>							
	IAAS sets before the ACK bit. The CPU must check the SRW bit and set TX/RX accordingly. Writing the C1 register with any value clears this bit. 0 Not addressed							
	1 Addressed as a slave							
5 BUSY	Bus Busy Indicates the status of the bus regardless of slave or master mode. This bit is set when a START signal is detected and cleared when a STOP signal is detected.							
	0 Bus is idle 1 Bus is busy							
4 ARBL	<ul> <li>Arbitration Lost</li> <li>This bit is set by hardware when the arbitration procedure is lost. The ARBL bit must be cleared by software, by writing 1 to it.</li> <li>0 Standard bus operation.</li> </ul>							
3	1     Loss of arbitration.       Range Address Match							
RAM	<ul> <li>This bit is set to 1 by any of the following conditions, if I2C_C2[RMEN] = 1:</li> <li>Any nonzero calling address is received that matches the address in the RA register.</li> <li>The calling address is within the range of values of the A1 and RA registers.</li> </ul>							
	Writing the C1 register with any value clears this bit to 0.							
	<ul><li>0 Not addressed</li><li>1 Addressed as a slave</li></ul>							
2 SRW	Slave Read/Write							
	When addressed as a slave, SRW indicates the value of the R/W command bit of the calling address sent to the master.							
	<ol> <li>Slave receive, master writing to slave</li> <li>Slave transmit, master reading from slave</li> </ol>							
1 IICIF	Interrupt Flag							
	<ul> <li>This bit sets when an interrupt is pending. This bit must be cleared by software by writing 1 to it, such as in the interrupt routine. One of the following events can set this bit:</li> <li>One byte transfer, including ACK/NACK bit, completes if FACK is 0. An ACK or NACK is sent on the bus by writing 0 or 1 to TXAK after this bit is set in receive mode.</li> <li>One byte transfer, excluding ACK/NACK bit, completes if FACK is 1.</li> </ul>							

## I2C\_S field descriptions (continued)

Table continues on the next page ...

Field	Description						
	<ul> <li>Match of slave address to calling address including primary slave address, range slave address, alert response address, second slave address, or general call address.</li> <li>Arbitration lost</li> <li>In SMBus mode, any timeouts except SCL and SDA high timeouts</li> <li>I2C bus stop or start detection if the SSIE bit in the Input Glitch Filter register is 1</li> </ul>						
	<b>NOTE:</b> To clear the I2C bus stop or start detection interrupt: In the interrupt service routine, first clear the STOPF or STARTF bit in the Input Glitch Filter register by writing 1 to it, and then clear the IICIF bit. If this sequence is reversed, the IICIF bit is asserted again.						
	0 No interrupt pending						
	1 Interrupt pending						
0 BXAK	Receive Acknowledge						
	<ol> <li>Acknowledge signal was received after the completion of one byte of data transmission on the bus</li> <li>No acknowledge signal detected</li> </ol>

## 19.4.5 I2C Data I/O register (I2C\_D)

Address: 3070h base + 4h offset = 3074h

Bit	7	6	5	4	3	2	1	0
Read Write				DA	TA			
Reset	0	0	0	0	0	0	0	0

### I2C\_D field descriptions

Field	Description
DATA	Data
	In master transmit mode, when data is written to this register, a data transfer is initiated. The most significant bit is sent first. In master receive mode, reading this register initiates receiving of the next byte of data.
	<b>NOTE:</b> When making the transition out of master receive mode, switch the I2C mode before reading the Data register to prevent an inadvertent initiation of a master receive data transfer.
	In slave mode, the same functions are available after an address match occurs.
	The C1[TX] bit must correctly reflect the desired direction of transfer in master and slave modes for the transmission to begin. For example, if the I2C module is configured for master transmit but a master receive is desired, reading the Data register does not initiate the receive.
	Reading the Data register returns the last byte received while the I2C module is configured in master receive or slave receive mode. The Data register does not reflect every byte that is transmitted on the I2C bus, and neither can software verify that a byte has been written to the Data register correctly by reading it back.
	In master transmit mode, the first byte of data written to the Data register following assertion of MST (start bit) or assertion of RSTA (repeated start bit) is used for the address transfer and must consist of the calling address (in bits 7-1) concatenated with the required R/W bit (in position bit 0).

# 19.4.6 I2C Control Register 2 (I2C\_C2)

Address: 3070h base + 5h offset = 3075h

Bit	7	6	5	4	3	2	1	0
Read Write	GCAEN	ADEXT	0	SBRC	RMEN		AD[10:8]	
Reset	0	0	0	0	0	0	0	0

### I2C\_C2 field descriptions

Field	Description
7 GCAEN	General Call Address Enable Enables general call address.
	0 Disabled 1 Enabled
6 ADEXT	<ul> <li>Address Extension</li> <li>Controls the number of bits used for the slave address.</li> <li>7-bit address scheme</li> <li>10-bit address scheme</li> </ul>
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 SBRC	<ul> <li>Slave Baud Rate Control</li> <li>Enables independent slave mode baud rate at maximum frequency, which forces clock stretching on SCL in very fast I2C modes. To a slave, an example of a "very fast" mode is when the master transfers at 40 kbit/s but the slave can capture the master's data at only 10 kbit/s.</li> <li>0 The slave baud rate follows the master baud rate and clock stretching may occur</li> <li>1 Slave baud rate is independent of the master baud rate</li> </ul>
3 RMEN	<ul> <li>Range Address Matching Enable</li> <li>This bit controls the slave address matching for addresses between the values of the A1 and RA registers. When this bit is set, a slave address matching occurs for any address greater than the value of the A1 register and less than or equal to the value of the RA register.</li> <li>Range mode disabled. No address matching occurs for an address within the range of values of the A1 and RA registers.</li> <li>Range mode enabled. Address matching occurs when a slave receives an address within the range of values of the A1 and RA registers.</li> </ul>
AD[10:8]	Slave Address Contains the upper three bits of the slave address in the 10-bit address scheme. This field is valid only while the ADEXT bit is set.

## 19.4.7 I2C Programmable Input Glitch Filter Register (I2C\_FLT)

Bit	7	6	5	4	3	2	1	0
Read	SHEN	STOPF	0015	STARTF				
Write		w1c	SSIE	w1c	c		FLT	
Reset	0	0	0	0	0	0	0	0

### I2C\_FLT field descriptions

Field	Description
7 SHEN	Stop Hold Enable
SHEN	Set this bit to hold off entry to stop mode when any data transmission or reception is occurring. The following scenario explains the holdoff functionality:
	<ol> <li>The I2C module is configured for a basic transfer, and the SHEN bit is set to 1.</li> <li>A transfer begins.</li> </ol>
	<ol> <li>The MCU signals the I2C module to enter stop mode.</li> <li>The byte currently being transferred, including both address and data, completes its transfer.</li> <li>The I2C slave or master acknowledges that the in-transfer byte completed its transfer and acknowledges the request to enter stop mode.</li> <li>After receiving the I2C module's acknowledgment of the request to enter stop mode, the MCU</li> </ol>
	determines whether to shut off the I2C module's clock.
	If the SHEN bit is set to 1 and the I2C module is in an idle or disabled state when the MCU signals to enter stop mode, the module immediately acknowledges the request to enter stop mode.
	If SHEN is cleared to 0 and the overall data transmission or reception that was suspended by stop mode entry was incomplete: To resume the overall transmission or reception after the MCU exits stop mode, software must reinitialize the transfer by resending the address of the slave.
	If the I2C Control Register 1's IICIE bit was set to 1 before the MCU entered stop mode, system software will receive the interrupt triggered by the I2C Status Register's TCF bit after the MCU wakes from the stop mode.
	<ul><li>0 Stop holdoff is disabled. The MCU's entry to stop mode is not gated.</li><li>1 Stop holdoff is enabled.</li></ul>
6 STOPF	I2C Bus Stop Detect Flag
	Hardware sets this bit when the I2C bus's stop status is detected. The STOPF bit must be cleared by writing 1 to it.
	NOTE: The stop flag is only for the matched slave devices, therefore the master will not respond for it.
	0 No stop happens on I2C bus
	1 Stop detected on I2C bus
5 SSIE	I2C Bus Stop or Start Interrupt Enable
301E	This bit enables the interrupt for I2C bus stop or start detection.
	<b>NOTE:</b> To clear the I2C bus stop or start detection interrupt: In the interrupt service routine, first clear the STOPF or STARTF bit by writing 1 to it, and then clear the IICIF bit in the status register. If this sequence is reversed, the IICIF bit is asserted again.

Table continues on the next page ...

Field	Description
	0 Stop or start detection interrupt is disabled
	1 Stop or start detection interrupt is enabled
4 STARTF	I2C Bus Start Detect Flag
START	Hardware sets this bit when the I2C bus's start status is detected. The STARTF bit must be cleared by writing 1 to it.
	0 No start happens on I2C bus
	1 Start detected on I2C bus
FLT	I2C Programmable Filter Factor
	Controls the width of the glitch, in terms of I2C module clock cycles, that the filter must absorb. For any glitch whose size is less than or equal to this width setting, the filter does not allow the glitch to pass.
	0h No filter/bypass
	1-Fh Filter glitches up to width of <i>n</i> I2C module clock cycles, where <i>n</i> =1-15d

### I2C\_FLT field descriptions (continued)

# 19.4.8 I2C Range Address register (I2C\_RA)

Address: 3070h base + 7h offset = 3077h

Bit	7	6	5	4	3	2	1	0
Read Write				RAD				0
Reset	0	0	0	0	0	0	0	0

### I2C\_RA field descriptions

Field	Description
7–1 RAD	Range Slave Address This field contains the slave address to be used by the I2C module. The field is used in the 7-bit address scheme. If I2C_C2[RMEN] is set to 1, any nonzero value write enables this register. This register value can be considered as a maximum boundary in the range matching mode.
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

# **19.4.9** I2C SMBus Control and Status register (I2C\_SMB)

## NOTE

When the SCL and SDA signals are held high for a length of time greater than the high timeout period, the SHTF1 flag sets. Before reaching this threshold, while the system is detecting how long these signals are being held high, a master assumes that the bus is free. However, the SHTF1 bit is set to 1 in the bus transmission process with the idle bus state.

### NOTE

When the TCKSEL bit is set, there is no need to monitor the SHTF1 bit because the bus speed is too high to match the protocol of SMBus.

Address: 3070h base + 8h offset = 3078h

Bit	7	6	5	4	3	2	1	0
Read	FACK	ALERTEN	SIICAEN	TCKSEL	SLTF	SHTF1	SHTF2	SHTF2IE
Write	FACK	ALCHICK	SIICAEN	TORGEL	w1c		w1c	SITTZIE
Reset	0	0	0	0	0	0	0	0

### I2C\_SMB field descriptions

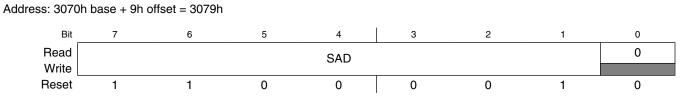

Field	Description
7 FACK	Fast NACK/ACK Enable
	For SMBus packet error checking, the CPU must be able to issue an ACK or NACK according to the result of receiving data byte.
	0 An ACK or NACK is sent on the following receiving data byte
	1 Writing 0 to TXAK after receiving a data byte generates an ACK. Writing 1 to TXAK after receiving a data byte generates a NACK.
6 ALERTEN	SMBus Alert Response Address Enable
	Enables or disables SMBus alert response address matching.
	<b>NOTE:</b> After the host responds to a device that used the alert response address, you must use software to put the device's address on the bus. The alert protocol is described in the SMBus specification.
	0 SMBus alert response address matching is disabled
	1 SMBus alert response address matching is enabled
5 SIICAEN	Second I2C Address Enable
	Enables or disables SMBus device default address.
	0 I2C address register 2 matching is disabled
	1 I2C address register 2 matching is enabled

Table continues on the next page ...

I2C_SMB field descriptions	(continued)
----------------------------	-------------

Field	Description							
4 TCKSEL	Timeout Counter Clock Select							
TOROLL	Selects the clock source of the timeout counter.							
	0 Timeout counter counts at the frequency of the I2C module clock / 64							
	1 Timeout counter counts at the frequency of the I2C module clock							
3 SLTF	SCL Low Timeout Flag							
	This bit is set when the SLT register (consisting of the SLTH and SLTL registers) is loaded with a non-zero value (LoValue) and an SCL low timeout occurs. Software clears this bit by writing a logic 1 to it.							
	<b>NOTE:</b> The low timeout function is disabled when the SLT register's value is 0.							
	0 No low timeout occurs							
	1 Low timeout occurs							
2 SHTF1	SCL High Timeout Flag 1							
	This read-only bit sets when SCL and SDA are held high more than clock × LoValue / 512, which indicates the bus is free. This bit is cleared automatically.							
	0 No SCL high and SDA high timeout occurs							
	1 SCL high and SDA high timeout occurs							
1	SCL High Timeout Flag 2							
SHTF2	This bit sets when SCL is held high and SDA is held low more than clock × LoValue / 512. Software clears this bit by writing 1 to it.							
	0 No SCL high and SDA low timeout occurs							
	1 SCL high and SDA low timeout occurs							
0 SHTF2IE	SHTF2 Interrupt Enable							
	Enables SCL high and SDA low timeout interrupt.							
	0 SHTF2 interrupt is disabled							
	1 SHTF2 interrupt is enabled							

## 19.4.10 I2C Address Register 2 (I2C\_A2)

### I2C\_A2 field descriptions

Field	Description
7–1 SAD	SMBus Address

Table continues on the next page ...

Field	Description
	Contains the slave address used by the SMBus. This field is used on the device default address or other related addresses.
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

### I2C\_A2 field descriptions (continued)

## 19.4.11 I2C SCL Low Timeout Register High (I2C\_SLTH)

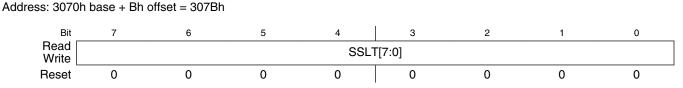

Address: 3070h base + Ah offset = 307Ah

Bit	7	6	5	4	3	2	1	0
Read Write	SSLT[15:8]							
Reset	0	0	0	0	0	0	0	0

### I2C\_SLTH field descriptions

Field	Description
SSLT[15:8]	SSLT[15:8]
	Most significant byte of SCL low timeout value that determines the timeout period of SCL low.

## 19.4.12 I2C SCL Low Timeout Register Low (I2C\_SLTL)

#### I2C\_SLTL field descriptions

Field	Description
SSLT[7:0]	SSLT[7:0]
	Least significant byte of SCL low timeout value that determines the timeout period of SCL low.

# 19.5 Functional description

This section provides a comprehensive functional description of the I2C module.

# 19.5.1 I2C protocol

The I2C bus system uses a serial data line (SDA) and a serial clock line (SCL) for data transfers.

All devices connected to it must have open drain or open collector outputs. A logic AND function is exercised on both lines with external pull-up resistors. The value of these resistors depends on the system.

Normally, a standard instance of communication is composed of four parts:

- 1. START signal
- 2. Slave address transmission
- 3. Data transfer
- 4. STOP signal

The STOP signal should not be confused with the CPU STOP instruction. The following figure illustrates I2C bus system communication.

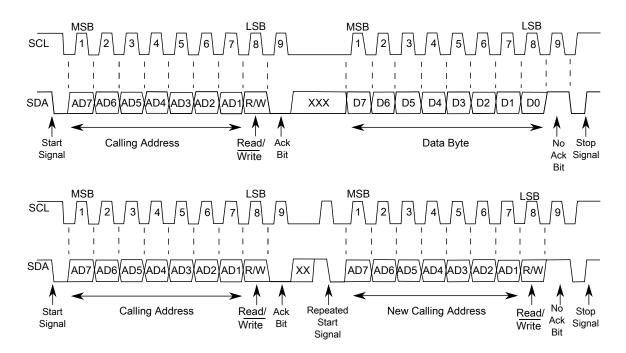

Figure 19-2. I2C bus transmission signals

## 19.5.1.1 START signal

The bus is free when no master device is engaging the bus (both SCL and SDA are high). When the bus is free, a master may initiate communication by sending a START signal. A START signal is defined as a high-to-low transition of SDA while SCL is high. This signal denotes the beginning of a new data transfer—each data transfer might contain several bytes of data—and brings all slaves out of their idle states.

## 19.5.1.2 Slave address transmission

Immediately after the START signal, the first byte of a data transfer is the slave address transmitted by the master. This address is a 7-bit calling address followed by an  $R/\overline{W}$  bit. The  $R/\overline{W}$  bit tells the slave the desired direction of data transfer.

- 1 = Read transfer: The slave transmits data to the master
- 0 = Write transfer: The master transmits data to the slave

Only the slave with a calling address that matches the one transmitted by the master responds by sending an acknowledge bit. The slave sends the acknowledge bit by pulling SDA low at the ninth clock.

No two slaves in the system can have the same address. If the I2C module is the master, it must not transmit an address that is equal to its own slave address. The I2C module cannot be master and slave at the same time. However, if arbitration is lost during an address cycle, the I2C module reverts to slave mode and operates correctly even if it is being addressed by another master.

# 19.5.1.3 Data transfers

When successful slave addressing is achieved, data transfer can proceed on a byte-bybyte basis in the direction specified by the  $R/\overline{W}$  bit sent by the calling master.

All transfers that follow an address cycle are referred to as data transfers, even if they carry subaddress information for the slave device.

Each data byte is 8 bits long. Data may be changed only while SCL is low. Data must be held stable while SCL is high. There is one clock pulse on SCL for each data bit, and the MSB is transferred first. Each data byte is followed by a ninth (acknowledge) bit, which is signaled from the receiving device by pulling SDA low at the ninth clock. In summary, one complete data transfer needs nine clock pulses.

#### Functional description

If the slave receiver does not acknowledge the master in the ninth bit, the slave must leave SDA high. The master interprets the failed acknowledgement as an unsuccessful data transfer.

If the master receiver does not acknowledge the slave transmitter after a data byte transmission, the slave interprets it as an end to data transfer and releases the SDA line.

In the case of a failed acknowledgement by either the slave or master, the data transfer is aborted and the master does one of two things:

- Relinquishes the bus by generating a STOP signal.
- Commences a new call by generating a repeated START signal.

# 19.5.1.4 STOP signal

The master can terminate the communication by generating a STOP signal to free the bus. A STOP signal is defined as a low-to-high transition of SDA while SCL is asserted.

The master can generate a STOP signal even if the slave has generated an acknowledgement, at which point the slave must release the bus.

# 19.5.1.5 Repeated START signal

The master may generate a START signal followed by a calling command without generating a STOP signal first. This action is called a repeated START. The master uses a repeated START to communicate with another slave or with the same slave in a different mode (transmit/receive mode) without releasing the bus.

## 19.5.1.6 Arbitration procedure

The I2C bus is a true multimaster bus that allows more than one master to be connected on it.

If two or more masters try to control the bus at the same time, a clock synchronization procedure determines the bus clock. The bus clock's low period is equal to the longest clock low period, and the high period is equal to the shortest one among the masters.

The relative priority of the contending masters is determined by a data arbitration procedure. A bus master loses arbitration if it transmits logic level 1 while another master transmits logic level 0. The losing masters immediately switch to slave receive mode and

stop driving SDA output. In this case, the transition from master to slave mode does not generate a STOP condition. Meanwhile, hardware sets a status bit to indicate the loss of arbitration.

## 19.5.1.7 Clock synchronization

Because wire AND logic is performed on SCL, a high-to-low transition on SCL affects all devices connected on the bus. The devices start counting their low period and, after a device's clock has gone low, that device holds SCL low until the clock reaches its high state. However, the change of low to high in this device clock might not change the state of SCL if another device clock is still within its low period. Therefore, the synchronized clock SCL is held low by the device with the longest low period. Devices with shorter low periods enter a high wait state during this time; see the following diagram. When all applicable devices have counted off their low period, the synchronized clock SCL is released and pulled high. Afterward there is no difference between the device clocks and the state of SCL, and all devices start counting their high periods. The first device to complete its high period pulls SCL low again.

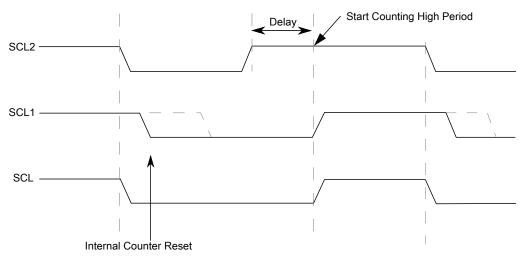

Figure 19-3. I2C clock synchronization

## 19.5.1.8 Handshaking

The clock synchronization mechanism can be used as a handshake in data transfers. A slave device may hold SCL low after completing a single byte transfer (9 bits). In this case, it halts the bus clock and forces the master clock into wait states until the slave releases SCL.

Functional description

## 19.5.1.9 Clock stretching

The clock synchronization mechanism can be used by slaves to slow down the bit rate of a transfer. After the master drives SCL low, a slave can drive SCL low for the required period and then release it. If the slave's SCL low period is greater than the master's SCL low period, the resulting SCL bus signal's low period is stretched. In other words, the SCL bus signal's low period is increased to be the same length as the slave's SCL low period.

## 19.5.1.10 I2C divider and hold values

NOTE

For some cases on some devices, the SCL divider value may vary by  $\pm 2$  or  $\pm 4$  when ICR's value ranges from 00h to 0Fh. These potentially varying SCL divider values are highlighted in the following table.

ICR (hex)	SCL divider	SDA hold value	SCL hold (start) value	SCL hold (stop) value	ICR (hex)	SCL divider (clocks)	SDA hold (clocks)	SCL hold (start) value	SCL hold (stop) value
00	20	7	6	11	20	160	17	78	81
01	22	7	7	12	21	192	17	94	97
02	24	8	8	13	22	224	33	110	113

Table 19-3. I2C divider and hold values (continued)

## 19.5.2 10-bit address

For 10-bit addressing, 0x11110 is used for the first 5 bits of the first address byte. Various combinations of read/write formats are possible within a transfer that includes 10-bit addressing.

## 19.5.2.1 Master-transmitter addresses a slave-receiver

The transfer direction is not changed. When a 10-bit address follows a START condition, each slave compares the first 7 bits of the first byte of the slave address (11110XX) with its own address and tests whether the eighth bit ( $R/\overline{W}$  direction bit) is 0. It is possible that more than one device finds a match and generates an acknowledge (A1). Each slave that finds a match compares the 8 bits of the second byte of the slave address with its own address, but only one slave finds a match and generates an acknowledge (A2). The matching slave remains addressed by the master until it receives a STOP condition (P) or a repeated START condition (Sr) followed by a different slave address.

S	Slave address first 7 bits 11110 + AD10 + AD9	R/W 0	A1	Slave address second byte AD[8:1]	A2	Data	A		Data	A/A	Ρ
---	--	----------	----	---	----	------	---	--	------	-----	---

Table 19-4. Master-transmitter addresses slave-receiver with a 10-bit address

```
Functional description
```

After the master-transmitter has sent the first byte of the 10-bit address, the slave-receiver sees an I2C interrupt. User software must ensure that for this interrupt, the contents of the Data register are ignored and not treated as valid data.

## 19.5.2.2 Master-receiver addresses a slave-transmitter

The transfer direction is changed after the second  $R/\overline{W}$  bit. Up to and including acknowledge bit A2, the procedure is the same as that described for a master-transmitter addressing a slave-receiver. After the repeated START condition (Sr), a matching slave remembers that it was addressed before. This slave then checks whether the first seven bits of the first byte of the slave address following Sr are the same as they were after the START condition (S), and it tests whether the eighth ( $R/\overline{W}$ ) bit is 1. If there is a match, the slave considers that it has been addressed as a transmitter and generates acknowledge A3. The slave-transmitter remains addressed until it receives a STOP condition (P) or a repeated START condition (Sr) followed by a different slave address.

After a repeated START condition (Sr), all other slave devices also compare the first seven bits of the first byte of the slave address with their own addresses and test the eighth ( $R/\overline{W}$ ) bit. However, none of them are addressed because  $R/\overline{W} = 1$  (for 10-bit devices), or the 11110XX slave address (for 7-bit devices) does not match.

S	Slave address first 7 bits 11110 + AD10 + AD9	R/W 0	A1	Slave address second byte AD[8:1]	A2	Sr	Slave address first 7 bits 11110 + AD10 + AD9	R/W 1	A3	Data	A		Data	A	Ρ	
---	---	----------	----	---	----	----	---	----------	----	------	---	--	------	---	---	--

Table 19-5. Master-receiver addresses a slave-transmitter with a 10-bit address

After the master-receiver has sent the first byte of the 10-bit address, the slave-transmitter sees an I2C interrupt. User software must ensure that for this interrupt, the contents of the Data register are ignored and not treated as valid data.

# 19.5.3 Address matching

All received addresses can be requested in 7-bit or 10-bit address format.

- AD[7:1] in Address Register 1, which contains the I2C primary slave address, always participates in the address matching process. It provides a 7-bit address.
- If the ADEXT bit is set, AD[10:8] in Control Register 2 participates in the address matching process. It extends the I2C primary slave address to a 10-bit address.

Additional conditions that affect address matching include:

- If the GCAEN bit is set, general call participates the address matching process.
- If the ALERTEN bit is set, alert response participates the address matching process.
- If the SIICAEN bit is set, Address Register 2 participates in the address matching process.
- If the RMEN bit is set, when the Range Address register is programmed to a nonzero value, any address within the range of values of Address Register 1 (excluded) and the Range Address register (included) participates in the address matching process. The Range Address register must be programmed to a value greater than the value of Address Register 1.

When the I2C module responds to one of these addresses, it acts as a slave-receiver and the IAAS bit is set after the address cycle. Software must read the Data register after the first byte transfer to determine that the address is matched.

# 19.5.4 System management bus specification

SMBus provides a control bus for system and power management related tasks. A system can use SMBus to pass messages to and from devices instead of tripping individual control lines.

Removing the individual control lines reduces pin count. Accepting messages ensures future expandability. With the system management bus, a device can provide manufacturer information, tell the system what its model/part number is, save its state for a suspend event, report different types of errors, accept control parameters, and return its status.

# 19.5.4.1 Timeouts

The  $T_{TIMEOUT,MIN}$  parameter allows a master or slave to conclude that a defective device is holding the clock low indefinitely or a master is intentionally trying to drive devices off the bus. The slave device must release the bus (stop driving the bus and let SCL and SDA float high) when it detects any single clock held low longer than  $T_{TIMEOUT,MIN}$ . Devices that have detected this condition must reset their communication and be able to receive a new START condition within the timeframe of  $T_{TIMEOUT,MAX}$ .

SMBus defines a clock low timeout,  $T_{TIMEOUT}$ , of 35 ms, specifies  $T_{LOW:SEXT}$  as the cumulative clock low extend time for a slave device, and specifies  $T_{LOW:MEXT}$  as the cumulative clock low extend time for a master device.

## 19.5.4.1.1 SCL low timeout

If the SCL line is held low by a slave device on the bus, no further communication is possible. Furthermore, the master cannot force the SCL line high to correct the error condition. To solve this problem, the SMBus protocol specifies that devices participating in a transfer must detect any clock cycle held low longer than a timeout value condition. Devices that have detected the timeout condition must reset the communication. When the I2C module is an active master, if it detects that SMBCLK low has exceeded the value of  $T_{TIMEOUT,MIN}$ , it must generate a stop condition within or after the current data byte in the transfer process. When the I2C module is a slave, if it detects the T<sub>TIMEOUT,MIN</sub> condition, it resets its communication and is then able to receive a new START condition.

## 19.5.4.1.2 SCL high timeout

When the I2C module has determined that the SMBCLK and SMBDAT signals have been high for at least  $T_{HIGH:MAX}$ , it assumes that the bus is idle.

A HIGH timeout occurs after a START condition appears on the bus but before a STOP condition appears on the bus. Any master detecting this scenario can assume the bus is free when either of the following occurs:

- SHTF1 rises.
- The BUSY bit is high and SHTF1 is high.

When the SMBDAT signal is low and the SMBCLK signal is high for a period of time, another kind of timeout occurs. The time period must be defined in software. SHTF2 is used as the flag when the time limit is reached. This flag is also an interrupt resource, so it triggers IICIF.

## 19.5.4.1.3 CSMBCLK TIMEOUT MEXT and CSMBCLK TIMEOUT SEXT

The following figure illustrates the definition of the timeout intervals  $T_{LOW:SEXT}$  and  $T_{LOW:MEXT}$ . When in master mode, the I2C module must not cumulatively extend its clock cycles for a period greater than  $T_{LOW:MEXT}$  within a byte, where each byte is defined as START-to-ACK, ACK-to-ACK, or ACK-to-STOP. When CSMBCLK TIMEOUT MEXT occurs, SMBus MEXT rises and also triggers the SLTF.

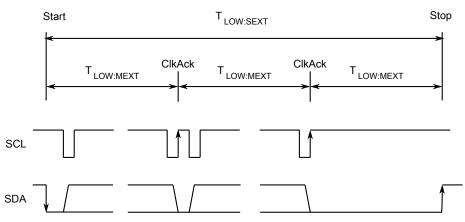

Figure 19-4. Timeout measurement intervals

A master is allowed to abort the transaction in progress to any slave that violates the  $T_{LOW:SEXT}$  or  $T_{TIMEOUT,MIN}$  specifications. To abort the transaction, the master issues a STOP condition at the conclusion of the byte transfer in progress. When a slave, the I2C module must not cumulatively extend its clock cycles for a period greater than  $T_{LOW:SEXT}$  during any message from the initial START to the STOP. When CSMBCLK TIMEOUT SEXT occurs, SEXT rises and also triggers SLTF.

**NOTE** CSMBCLK TIMEOUT SEXT and CSMBCLK TIMEOUT MEXT are optional functions that are implemented in the second step.

# 19.5.4.2 FAST ACK and NACK

To improve reliability and communication robustness, implementation of packet error checking (PEC) by SMBus devices is optional for SMBus devices but required for devices participating in and only during the address resolution protocol (ARP) process. The PEC is a CRC-8 error checking byte, calculated on all the message bytes. The PEC is appended to the message by the device that supplied the last data byte. If the PEC is present but not correct, a NACK is issued by the receiver. Otherwise an ACK is issued. To calculate the CRC-8 by software, this module can hold the SCL line low after receiving the eighth SCL (8th bit) if this byte is a data byte. So software can determine whether an ACK or NACK should be sent to the bus by setting or clearing the TXAK bit if the FACK (fast ACK/NACK enable) bit is enabled.

SMBus requires a device always to acknowledge its own address, as a mechanism to detect the presence of a removable device (such as a battery or docking station) on the bus. In addition to indicating a slave device busy condition, SMBus uses the NACK mechanism to indicate the reception of an invalid command or invalid data. Because such a condition may occur on the last byte of the transfer, SMBus devices are required to

#### **Functional description**

have the ability to generate the not acknowledge after the transfer of each byte and before the completion of the transaction. This requirement is important because SMBus does not provide any other resend signaling. This difference in the use of the NACK signaling has implications on the specific implementation of the SMBus port, especially in devices that handle critical system data such as the SMBus host and the SBS components.

### NOTE

In the last byte of master receive slave transmit mode, the master must send a NACK to the bus, so FACK must be switched off before the last byte transmits.

## 19.5.5 Resets

The I2C module is disabled after a reset. The I2C module cannot cause a core reset.

## 19.5.6 Interrupts

The I2C module generates an interrupt when any of the events in the table found here occur, provided that the IICIE bit is set.

The interrupt is driven by the IICIF bit (of the I2C Status Register) and masked with the IICIE bit (of the I2C Control Register 1). The IICIF bit must be cleared (by software) by writing 1 to it in the interrupt routine. The SMBus timeouts interrupt is driven by SLTF and masked with the IICIE bit. The SLTF bit must be cleared by software by writing 1 to it in the interrupt routine. You can determine the interrupt type by reading the Status Register.

### NOTE

In master receive mode, the FACK bit must be set to zero before the last byte transfer.

Interrupt source	Status	Flag	Local enable
Complete 1-byte transfer	TCF	liCIF	IICIE
Match of received calling address	IAAS	liCIF	IICIE
Arbitration lost	ARBL	licif	IICIE
I <sup>2</sup> C bus stop detection	STOPF	licif	IICIE & SSIE
I <sup>2</sup> C bus start detection	STARTF	licif	IICIE & SSIE
SMBus SCL low timeout	SLTF	licif	IICIE
SMBus SCL high SDA low timeout	SHTF2	licif	IICIE & SHTF2IE
Wakeup from stop3 or wait mode	IAAS	licif	IICIE & WUEN

Table 19-6. Interrupt summary

## 19.5.6.1 Byte transfer interrupt

The Transfer Complete Flag (TCF) bit is set at the falling edge of the ninth clock to indicate the completion of a byte and acknowledgement transfer. When FACK is enabled, TCF is then set at the falling edge of eighth clock to indicate the completion of byte.

## 19.5.6.2 Address detect interrupt

When the calling address matches the programmed slave address (I2C Address Register) or when the GCAEN bit is set and a general call is received, the IAAS bit in the Status Register is set. The CPU is interrupted, provided the IICIE bit is set. The CPU must check the SRW bit and set its Tx mode accordingly.

## 19.5.6.3 Stop Detect Interrupt

When the stop status is detected on the  $I^2C$  bus, the STOPF bit is set to 1. The CPU is interrupted, provided the IICIE and SSIE bits are both set to 1.

## **19.5.6.4** Exit from low-power/stop modes

The slave receive input detect circuit and address matching feature are still active on low power modes (wait and stop). An asynchronous input matching slave address or general call address brings the CPU out of low power/stop mode if the interrupt is not masked. Therefore, TCF and IAAS both can trigger this interrupt.

## 19.5.6.5 Arbitration lost interrupt

The I2C is a true multimaster bus that allows more than one master to be connected on it. If two or more masters try to control the bus at the same time, the relative priority of the contending masters is determined by a data arbitration procedure. The I2C module asserts the arbitration-lost interrupt when it loses the data arbitration process and the ARBL bit in the Status Register is set.

Arbitration is lost in the following circumstances:

1. SDA is sampled as low when the master drives high during an address or data transmit cycle.

- 2. SDA is sampled as low when the master drives high during the acknowledge bit of a data receive cycle.
- 3. A START cycle is attempted when the bus is busy.
- 4. A repeated START cycle is requested in slave mode.
- 5. A STOP condition is detected when the master did not request it.

The ARBL bit must be cleared (by software) by writing 1 to it.

## 19.5.6.6 Timeout interrupt in SMBus

When the IICIE bit is set, the I2C module asserts a timeout interrupt (outputs SLTF and SHTF2) upon detection of any of the mentioned timeout conditions, with one exception. The SCL high and SDA high TIMEOUT mechanism must not be used to influence the timeout interrupt output, because this timeout indicates an idle condition on the bus. SHTF1 rises when it matches the SCL high and SDA high TIMEOUT and falls automatically just to indicate the bus status. The SHTF2's timeout period is the same as that of SHTF1, which is short compared to that of SLTF, so another control bit, SHTF2IE, is added to enable or disable it.

## 19.5.7 Programmable input glitch filter

An I2C glitch filter has been added outside legacy I2C modules but within the I2C package. This filter can absorb glitches on the I2C clock and data lines for the I2C module.

The width of the glitch to absorb can be specified in terms of the number of (half) I2C module clock cycles. A single Programmable Input Glitch Filter control register is provided. Effectively, any down-up-down or up-down-up transition on the data line that occurs within the number of clock cycles programmed in this register is ignored by the I2C module. The programmer must specify the size of the glitch (in terms of I2C module clock cycles) for the filter to absorb and not pass.

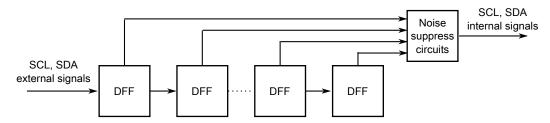

Figure 19-5. Programmable input glitch filter diagram

# 19.5.8 Address matching wake-up

When a primary, range, or general call address match occurs when the I2C module is in slave receive mode, the MCU wakes from a low power mode where no peripheral bus is running.

Data sent on the bus that is the same as a target device address might also wake the target MCU.

After the address matching IAAS bit is set, an interrupt is sent at the end of address matching to wake the core. The IAAS bit must be cleared after the clock recovery.

### NOTE

After the system recovers and is in Run mode, restart the I2C module if it is needed to transfer packets. To avoid I2C transfer problems resulting from the situation, firmware should prevent the MCU execution of a STOP instruction when the I2C module is in the middle of a transfer unless the Stop mode holdoff feature is used during this period (set FLT[SHEN] to 1).

# **19.6 Initialization/application information**

Module Initialization (Slave)

- 1. Write: Control Register 2
  - to enable or disable general call
  - to select 10-bit or 7-bit addressing mode
- 2. Write: Address Register 1 to set the slave address
- 3. Write: Control Register 1 to enable the I2C module and interrupts
- 4. Initialize RAM variables (IICEN = 1 and IICIE = 1) for transmit data
- 5. Initialize RAM variables used to achieve the routine shown in the following figure

Module Initialization (Master)

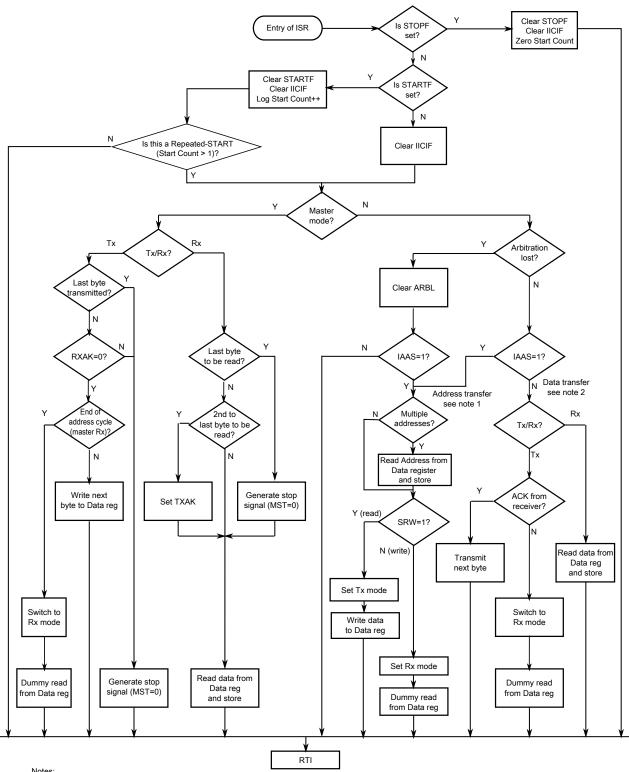

- 1. Write: Frequency Divider register to set the I2C baud rate (see example in description of ICR)
- 2. Write: Control Register 1 to enable the I2C module and interrupts
- 3. Initialize RAM variables (IICEN = 1 and IICIE = 1) for transmit data
- 4. Initialize RAM variables used to achieve the routine shown in the following figure
- 5. Write: Control Register 1 to enable TX

Initialization/application information

- 6. Write: Control Register 1 to enable MST (master mode)
- 7. Write: Data register with the address of the target slave (the LSB of this byte determines whether the communication is master receive or transmit)

The routine shown in the following figure encompasses both master and slave I2C operations. For slave operation, an incoming I2C message that contains the proper address begins I2C communication. For master operation, communication must be initiated by writing the Data register. An example of an I2C driver which implements many of the steps described here is available in AN4342: Using the Inter-Integrated Circuit on ColdFire+ and Kinetis .

Chapter 19 Inter-Integrated Circuit (I2C)

Notes:

1. If general call is enabled, check to determine if the received address is a general call address (0x00).

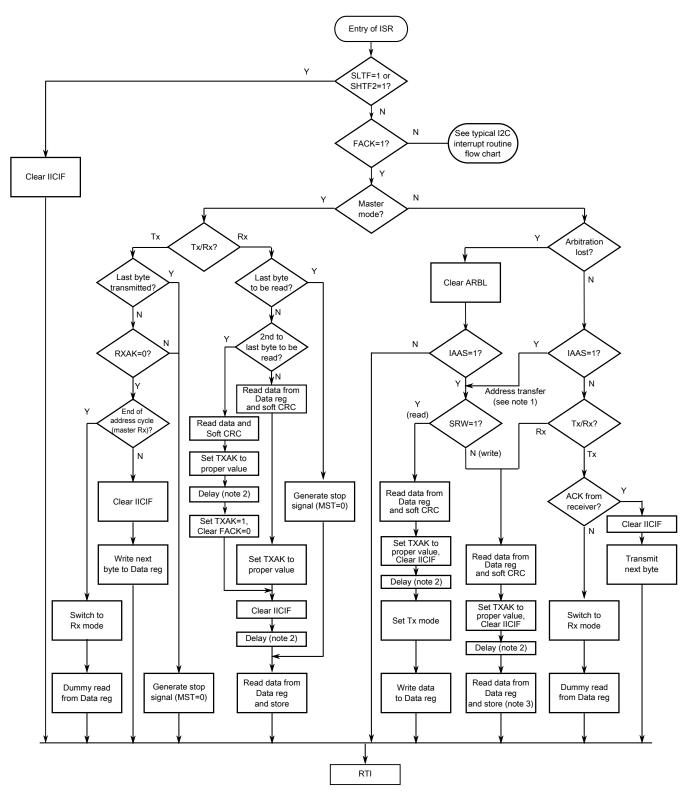

If the received address is a general call address, the general call must be handled by user software.

2. When 10-bit addressing addresses a slave, the slave sees an interrupt following the first byte of the extended address.

Ensure that for this interrupt, the contents of the Data register are ignored and not treated as a valid data transfer.

### Figure 19-6. Typical I2C interrupt routine

Notes:

- 1. If general call or SIICAEN is enabled, check to determine if the received address is a general call address (0x00) or an SMBus device default address. In either case, they must be handled by user software.
- 2. In receive mode, one bit time delay may be needed before the first and second data reading, to wait for the possible longest time period (in worst case) of the 9th SCL cycle.
- 3. This read is a dummy read in order to reset the SMBus receiver state machine.

### Figure 19-7. Typical I2C SMBus interrupt routine

# Chapter 20 Analog-to-digital converter (ADC)

## 20.1 Chip specific ADC information

This device contains one 10-bit analog-to-digital converter (ADC).

## 20.1.1 Channel assignments

The ADC channel assignments are shown in following table. Reserved channels convert to an unknown value.

ADCH	Channel	Input
00000	AD0	PTA0/ADP0
00001	AD1	PTA1/ADP1
00010	AD2	PTA2/ADP2
00011	AD3	PTA3/ADP3
00100	AD4	PTB0/ADP4
00101	AD5	PTB1/ADP5
00110	AD6	PTB2/ADP6
00111	AD7	PTB3/ADP7
01000	AD8	PTC0/ADP8
01001	AD9	PTC1/ADP9
01010	AD10	PTC2/ADP10
01011	AD11	PTC3/ADP11
01100	AD12	Reserved
01101	AD13	VSS
01110	AD14	VSS
01111	AD15	VSS
10000	AD16	VSS
10001	AD17	VSS

Table 20-1. ADC channel assignments

Table continues on the next page...

ADCH	Channel	Input
10010	AD18	VSS
10011	AD19	VSS
10100	AD20	Reserved
10101	AD21	Reserved
10110	AD22	Temperature Sensor
10111	AD23	Bandgap
11000	AD24	Reserved
11001	AD25	Reserved
11010	AD26	Reserved
11011	AD27	Reserved
11100	AD28	Reserved
11101	AD29	VREFH(VDD)
11110	AD30	VREFL(VSS)
11111	Module Disabled	None

 Table 20-1.
 ADC channel assignments (continued)

## 20.1.2 Alternate clock

The ADC module is capable of performing conversions using the MCU bus clock, the bus clock divided by two, the local asynchronous clock (ADACK) within the module, or the alternate clock, ALTCLK. The alternate clock for this device is the external oscillator output (OSCOUT).

The selected clock source must run at a frequency, so that the ADC conversion clock (ADCK) runs at a frequency within its specified range ( $f_{ADCK}$ ) after being divided down from the ALTCLK input as determined by the ADIV bits.

ALTCLK is active while the MCU is in wait mode provided the conditions described above are met. This allows ALTCLK to be used as the conversion clock source for the ADC while the MCU is in wait mode.

ALTCLK cannot be used as the ADC conversion clock source while the MCU is in stop3 mode.

## 20.1.3 Hardware trigger

The ADC hardware trigger, ADHWT, is selectable from RTC overflow, MTIM0 overflow, ACMP0 output, FTM0 Channel 0/1 or FTM2 Channel 0/1 with configurable edge. The hardware trigger can be configured to cause a hardware trigger in MCU run, wait, and stop3 modes. Refer to Figure 7-1.

## 20.1.4 Temperature sensor

The ADC module integrates an on-chip temperature sensor. Following actions must be performed to use this temperature sensor.

- Configure ADC for long sample with a maximum of 1 MHz clock
- Convert the bandgap voltage reference channel (AD23)
  - By converting the digital value of the bandgap voltage reference channel using the value of VBG the user can determine  $V_{DD}$ .
- Convert the temperature sensor channel (AD22)
  - By using the calculated value of VDD, convert the digital value of AD22 into a voltage,  $V_{\mbox{\scriptsize TEMP}}$

Following equation provides an approximate transfer function of the on-chip temperature sensor for VDD = 5.0V, Temp =25°C, using the ADC at  $f_{ADCK}$  = 1.0 MHz and configured for long sample.

## $Temp = 25 - ((V_{TEMP}-V_{TEMP25})/m)$

where:

- $V_{\text{TEMP}}$  is the voltage of the temperature sensor channel at the ambient temperature
- $V_{\text{TEMP25}}$  is the voltage of the temperature sensor channel at 25°C
- m is the hot or cold voltage versus temperature slope in V/°C

For temperature calculations, use the VTEMP25 and m values in the datasheet.

In application code, the user reads the temperature sensor channel, calculates  $V_{TEMP}$ , and compares it to  $V_{TEMP25}$ . If  $V_{TEMP}$  is greater than VTEMP25 the cold slope value is applied in above equation. If  $V_{TEMP}$  is less than  $V_{TEMP25}$  the hot slope value is applied in above equation.

# 20.2 Introduction

The 10-bit analog-to-digital converter (ADC) is a successive approximation ADC designed for operation within an integrated microcontroller system-on-chip.

#### MC9S08PL16S Reference Manual, Rev. 3, 06/2020

## 20.2.1 Features

Features of the ADC module include:

- Linear Successive Approximation algorithm with 8-, 10-bit resolution
- Up to 12 external analog inputs, external pin inputs, and 5 internal analog inputs including internal bandgap, temperature sensor, and references
- Output formatted in 8-, 10-bit right-justified unsigned format
- Single or Continuous Conversion (automatic return to idle after single conversion)
- Support up to eight result FIFO with selectable FIFO depth
- Configurable sample time and conversion speed/power
- Conversion complete flag and interrupt
- Input clock selectable from up to four sources
- Operation in Wait or Stop modes for lower noise operation
- Asynchronous clock source for lower noise operation
- Selectable asynchronous hardware conversion trigger
- Automatic compare with interrupt for less-than, or greater-than or equal-to, programmable value

## 20.2.2 Block Diagram

This figure provides a block diagram of the ADC module.

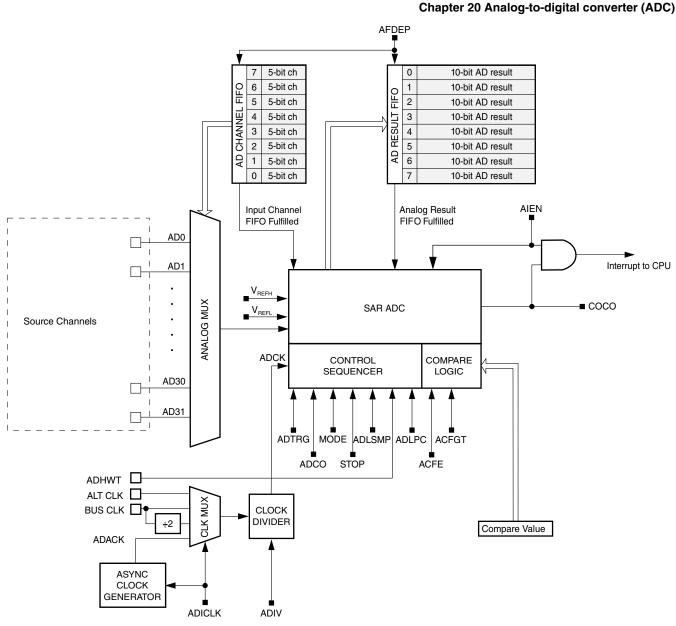

Figure 20-1. ADC Block Diagram

See chip specific sections for the channel assignments.

# 20.3 External Signal Description

The ADC module supports up to 12 separate analog inputs. It also requires four supply/ reference/ground connections.

Table 20-2.	Signal Properties
-------------	-------------------

Name	Function
AD11–AD0	Analog Channel inputs

Table continues on the next page ...

#### MC9S08PL16S Reference Manual, Rev. 3, 06/2020

**External Signal Description** 

Name	Function
V <sub>REFH</sub>	High reference voltage
V <sub>REFL</sub>	Low reference voltage
V <sub>DDA</sub>	Analog power supply
V <sub>SSA</sub>	Analog ground

 Table 20-2.
 Signal Properties (continued)

## 20.3.1 Analog Power (V<sub>DDA</sub>)

The ADC analog portion uses  $V_{DDA}$  as its power connection. In some packages,  $V_{DDA}$  is connected internally to  $V_{DDX}$ . If externally available, connect the  $V_{DDA}$  pin to the same voltage potential as  $V_{DDX}$ . External filtering may be necessary to ensure clean  $V_{DDA}$  for good results.

# 20.3.2 Analog Ground (V<sub>SSA</sub>)

The ADC analog portion uses  $V_{SSA}$  as its ground connection. In some packages,  $V_{SSA}$  is connected internally to  $V_{SS}$ . If externally available, connect the  $V_{SSA}$  pin to the same voltage potential as  $V_{SS}$ .

# 20.3.3 Voltage Reference High (V<sub>REFH</sub>)

 $V_{REFH}$  is the high reference voltage for the converter. In some packages,  $V_{REFH}$  is connected internally to  $V_{DDA}$ . If externally available,  $V_{REFH}$  may be connected to the same potential as  $V_{DDA}$  or may be driven by an external source between the minimum  $V_{DDA}$  specified in the data sheet and the  $V_{DDA}$  potential ( $V_{REFH}$  must never exceed  $V_{DDA}$ ).

# 20.3.4 Voltage Reference Low (V<sub>REFL</sub>)

 $V_{REFL}$  is the low-reference voltage for the converter. In some packages,  $V_{REFL}$  is connected internally to  $V_{SSA}$ . If externally available, connect the  $V_{REFL}$  pin to the same voltage potential as  $V_{SSA}$ .

# 20.3.5 Analog Channel Inputs (ADx)

The ADC module supports up to 24 separate analog inputs. An input is selected for conversion through the ADCH channel select bits.

# 20.4 ADC Control Registers

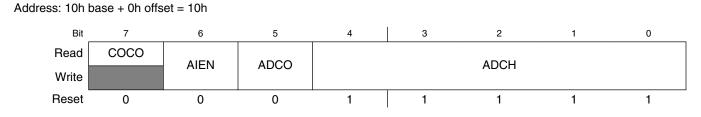

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
10	Status and Control Register 1 (ADC_SC1)	8	R/W	1Fh	20.4.1/331
11	Status and Control Register 2 (ADC_SC2)	8	R/W	08h	20.4.2/332
12	Status and Control Register 3 (ADC_SC3)	8	R/W	00h	20.4.3/334
13	Status and Control Register 4 (ADC_SC4)	8	R/W	00h	20.4.4/335
14	Conversion Result High Register (ADC_RH)	8	R	00h	20.4.5/336
15	Conversion Result Low Register (ADC_RL)	8	R	00h	20.4.6/337

#### ADC memory map

## 20.4.1 Status and Control Register 1 (ADC\_SC1)

This section describes the function of the ADC status and control register (ADC\_SC1). Writing ADC\_SC1 aborts the current conversion and initiates a new conversion (if the ADCH bits are equal to a value other than all 1s).

When FIFO is enabled, the analog input channel FIFO is written via ADCH. The analog input channel queue must be written to ADCH continuously. The resulting FIFO follows the order in which the analog input channel is written. The ADC will start conversion when the input channel FIFO is fulfilled at the depth indicated by the ADC\_SC4[AFDEP]. Any write 0x1F to these bits will reset the FIFO and stop the conversion if it is active.

MC9S08PL16S Reference Manual, Rev. 3, 06/2020

Field	Description					
7 COCO	Conversion Complete Flag					
	Conversion Complete Flag. The COCO flag is a read-only bit set each time a conversion is completed when the compare function is disabled (ADC_SC2[ACFE] = 0). When the compare function is enabled (ADC_SC2[ACFE] = 1), the COCO flag is set upon completion of a conversion only if the compare result is true. When the FIFO function is enabled (ADC_SC4[AFDEP] > 0), the COCO flag is set upon completion of the set of FIFO conversion. This bit is cleared when ADC_SC1 is written or when ADC_RL is read.					
	0 Conversion not completed.					
	1 Conversion completed.					
6 AIEN	Interrupt Enable					
	AIEN enables conversion complete interrupts. When COCO becomes set while AIEN is high, an interrupt is asserted.					
	0 Conversion complete interrupt disabled.					
	1 Conversion complete interrupt enabled.					
5 ADCO	Continuous Conversion Enable					
ADCO	ADCO enables continuous conversions.					
	0 One conversion following a write to the ADC_SC1 when software triggered operation is selected, or one conversion following assertion of ADHWT when hardware triggered operation is selected. When the FIFO function is enabled (AFDEP > 0), a set of conversions are triggered.					
	1 Continuous conversions are initiated following a write to ADC_SC1 when software triggered operation is selected. Continuous conversions are initiated by an ADHWT event when hardware triggered operation is selected. When the FIFO function is enabled (AFDEP > 0), a set of conversions are loop triggered.					
ADCH	Input Channel Select					
	The ADCH bits form a 5-bit field that selects one of the input channels. See chip specific section for the ADCH configurations.					

### ADC\_SC1 field descriptions

### 20.4.2 Status and Control Register 2 (ADC\_SC2)

The ADC\_SC2 register controls the compare function, conversion trigger, and conversion active of the ADC module.

Bit	7	6	5	4	3	2	1	0
Read	ADACT		ACFE	A055 A050T	FEMPTY	FFULL	REFSEL	
Write		ADTRG	ACFE	ACFGT			NER	SEL
Reset	0	0	0	0	1	0	0	0

Address: 10h base + 1h offset = 11h

ADC_SC	C2 field	descriptions
--------	----------	--------------

Field	Description
7 ADACT	Conversion Active
	Indicates that a conversion is in progress. ADACT is set when a conversion is initiated and cleared when a conversion is completed or aborted.
	0 Conversion not in progress.
	1 Conversion in progress.
6 ADTRG	Conversion Trigger Select
	Selects the type of trigger used for initiating a conversion. Two types of trigger are selectable: software trigger and hardware trigger. When software trigger is selected, a conversion is initiated following a write to ADC_SC1. When hardware trigger is selected, a conversion is initiated following the assertion of the ADHWT input.
	0 Software trigger selected.
	1 Hardware trigger selected.
5 ACFE	Compare Function Enable
	Enables the compare function.
	0 Compare function disabled.
	1 Compare function enabled.
4 ACFGT	Compare Function Greater Than Enable
	Configures the compare function to trigger when the result of the conversion of the input being monitored is greater than or equal to the compare value. The compare function defaults to triggering when the result of the compare of the input being monitored is less than the compare value.
	0 Compare triggers when input is less than compare level.
	1 Compare triggers when input is greater than or equal to compare level.
3 FEMPTY	Result FIFO empty
	0 Indicates that ADC result FIFO have at least one valid new data.
	1 Indicates that ADC result FIFO have no valid new data.
2 FFULL	Result FIFO full
	0 Indicates that ADC result FIFO is not full and next conversion data still can be stored into FIFO.
	1 Indicates that ADC result FIFO is full and next conversion will override old data in case of no read action.
REFSEL	Voltage Reference Selection
	Selects the voltage reference source used for conversions.
	00 Default voltage reference pin pair (V <sub>REFH</sub> /V <sub>REFL</sub> ).
	01 Analog supply pin pair (V <sub>DDA</sub> /V <sub>SSA</sub> ).
	10 Reserved.
	11 Reserved.

## 20.4.3 Status and Control Register 3 (ADC\_SC3)

ADC\_SC3 selects the mode of operation, clock source, clock divide, and configure for low power or long sample time.

Address: 10h base + 2h offset = 12h

Bit	7	6	5	4	3	2	1	0
Read Write	ADLPC	AD	VIV	ADLSMP	МС	DDE	ADI	CLK
Reset	0	0	0	0	0	0	0	0

#### ADC\_SC3 field descriptions

Field	Description
7	Low-Power Configuration
ADLPC	ADLPC controls the speed and power configuration of the successive approximation converter. This
	optimizes power consumption when higher sample rates are not required.
	0 High speed configuration.
	1 Low power configuration: The power is reduced at the expense of maximum clock speed.
6–5 ADIV	Clock Divide Select
ADIV	ADIV selects the divide ratio used by the ADC to generate the internal clock ADCK.
	00 Divide ration = 1, and clock rate = Input clock.
	01 Divide ration = 2, and clock rate = Input clock ÷ 2.
	10 Divide ration = 3, and clock rate = Input clock ÷ 4.
	11 Divide ration = 4, and clock rate = Input clock ÷ 8.
4 ADLSMP	Long Sample Time Configuration
	ADLSMP selects between long and short sample time. This adjusts the sample period to allow higher
	impedance inputs to be accurately sampled or to maximize conversion speed for lower impedance inputs. Longer sample times can also be used to lower overall power consumption when continuous conversions
	are enabled if high conversion rates are not required.
	0 Short sample time.
	1 Long sample time.
3–2	Conversion Mode Selection
MODE	MODE bits are used to select between 10-, or 8-bit operation.
	00 8-bit conversion (N=8)
	01 10-bit conversion (N=10)
	10 Reserved
	11 Reserved
ADICLK	Input Clock Select
	ADICLK bits select the input clock source to generate the internal clock ADCK.
	00 Bus clock
	01 Bus clock divided by 2
	The base of the second second

Field	Description			
	10 Alternate clock (ALTCLK)			
	11 Asynchronous clock (ADACK)			

## 20.4.4 Status and Control Register 4 (ADC\_SC4)

This register controls the FIFO scan mode, FIFO compare function and FIFO depth selection of the ADC module.

Address: 10h base + 3h offset = 13h

#### ADC\_SC4 field descriptions

Field	Description
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 ASCANE	FIFO Scan Mode Enable The FIFO always use the first dummied FIFO channels when it is enabled. When this bit is set and FIFO function is enabled, ADC will repeat using the first FIFO channel as the conversion channel until the result
	<ul> <li>FIFO is fulfilled. In continuous mode (ADCO = 1), ADC will start next conversion with the same channel when COCO is set.</li> <li>FIFO scan mode disabled.</li> <li>FIFO scan mode enabled.</li> </ul>
5 ACFSEL	Compare function select OR/AND when the FIFO function is enabled (AFDEP > 0). When this field is cleared, ADC will OR all of compare triggers and set COCO after at least one of compare trigger occurs. When this field is set, ADC will AND all of compare triggers and set COCO after all of compare triggers occur.
	<ul><li>0 OR all of compare trigger.</li><li>1 AND all of compare trigger.</li></ul>
4–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
AFDEP	FIFO Depth enables the FIFO function and sets the depth of FIFO. When AFDEP is cleared, the FIFO is disabled. When AFDEP is set to nonzero, the FIFO function is enabled and the depth is indicated by the AFDEP bits. The ADCH in ADC_SC1 and ADC_RH:ADC_RL must be accessed by FIFO mode when FIFO function is enabled. ADC starts conversion when the analog channel FIFO is upon the level indicated by AFDEP bits. The COCO bit is set when the set of conversions are completed and the result FIFO is upon the level indicated by AFDEP bits.
	<b>NOTE:</b> The bus clock frequency must be at least double the ADC clock when FIFO mode is enabled. It means, if ICS FBE mode is used, the ADC clock can not be ADACK.

Table continues on the next page...

	101 6-level FIFO is enabled.					
	110 7-level FIFO is enabled.					
	111 8-level FIFO is enabled.					

ADC\_SC4 field descriptions (continued)

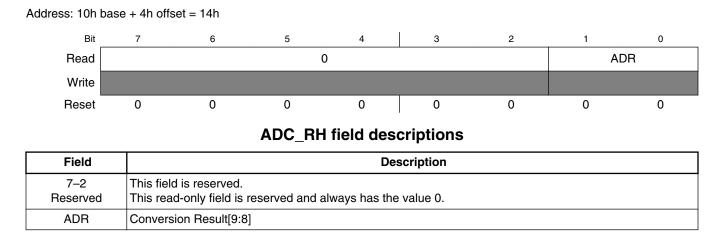

## 20.4.5 Conversion Result High Register (ADC\_RH)

In 10-bit mode, ADC\_RH contains the upper two bits of the result of a 10-bit conversion.

ADC\_RH is updated each time a conversion completes except when automatic compare is enabled and the compare condition is not met. Reading ADC\_RH prevents the ADC from transferring subsequent conversion results into the result registers until ADC\_RL is read. If ADC\_RL is not read until after the next conversion is completed, the intermediate conversion result is lost. In 8-bit mode, there is no interlocking with ADC\_RL.

When FIFO is enabled, the result FIFO is read via ADC\_RH:ADC\_RL. The ADC conversion completes when the input channel FIFO is fulfilled at the depth indicated by the AFDEP. The AD result FIFO can be read via ADC\_RH:ADC\_RL continuously by the order set in analog input channel ADCH.

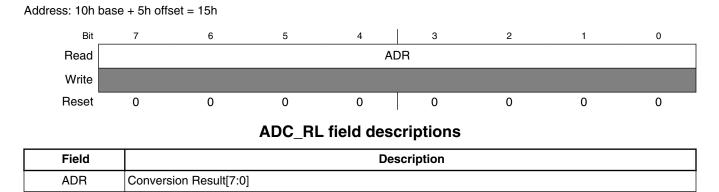

If the MODE bits are changed, any data in ADC\_RH becomes invalid.

## 20.4.6 Conversion Result Low Register (ADC\_RL)

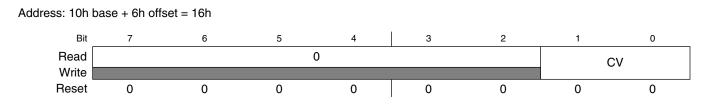

ADC\_RL contains the lower eight bits of the result of a 10-bit conversion. This register is updated each time a conversion completes except when automatic compare is enabled and the compare condition is not met. In 10-bit mode, reading ADC\_RH prevents the ADC from transferring subsequent conversion results into the result registers until ADC\_RL is read. If ADC\_RL is not read until the next conversion is completed, the intermediate conversion results are lost. In 8-bit mode, there is no interlocking with ADC\_RH. If the MODE bits are changed, any data in ADC\_RL becomes invalid.

When FIFO is enabled, the result FIFO is read via ADC\_RH:ADC\_RL. The ADC conversion completes when the input channel FIFO is fulfilled at the depth indicated by the AFDEP. The AD result FIFO can be read via ADC\_RH:ADC\_RL continuously by the order set in analog input channel FIFO.

## 20.4.7 Compare Value High Register (ADC\_CVH)

In 10-bit mode, this register holds the upper two bits of the 10-bit compare value. These bits are compared to the upper two bits of the result following a conversion in 10-bit mode when the compare function is enabled.

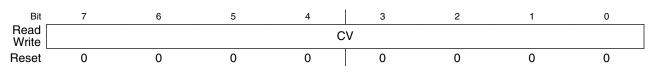

Field	Description			
7–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.			
CV	Conversion Result[9:8]			

### 20.4.8 Compare Value Low Register (ADC\_CVL)

This register holds the lower 8 bits of the 10-bit compare value. Bits CV7:CV0 are compared to the lower 8 bits of the result following a conversion in 10-bit mode.

Address: 10h base + 7h offset = 17h

#### ADC\_CVL field descriptions

Field	Description
CV	Conversion Result[7:0]

### 20.4.9 Pin Control 1 Register (ADC\_APCTL1)

The pin control registers disable the I/O port control of MCU pins used as analog inputs. APCTL1 is used to control the pins associated with channels 0-7 of the ADC module.

Address: 10h base + 309Ch offset = 30ACh

Bit	7	6	5	4	3	2	1	0

	ADPC8 controls the pin associated with channel AD8.
	0 AD8 pin I/O control enabled.
	1 AD8 pin I/O control disabled.

## 20.5 Functional description

The ADC module is disabled during reset or when the ADC\_SC1[ADCH] bits are all high. The module is idle when a conversion has completed and another conversion has not been initiated. When idle, the module is in its lowest power state.

#### Chapter 20 Analog-to-digital converter (ADC)

The ADC can perform an analog-to-digital conversion on any of the software selectable channels. In 10-bit mode, the selected channel voltage is converted by a successive approximation algorithm into a 10-bit digital result. In 8-bit mode, the selected channel voltage is converted by a successive approximation algorithm into a 8-bit digital result.

When the conversion is completed, the result is placed in the data registers (ADC\_RH and ADC\_RL). In 10-bit mode, the result is rounded to 10 bits and placed in the data registers (ADC\_RH and ADC\_RL). In 8-bit mode, the result is rounded to 8 bits and placed in ADC\_RL. The conversion complete flag (ADC\_SC1[COCO]) is then set and an interrupt is generated if the conversion complete interrupt has been enabled  $(ADC_SC1[AIEN] = 1)$ .

The ADC module has the capability of automatically comparing the result of a conversion with the contents of its compare registers. The compare function is enabled by setting the ADC\_SC2[ACFE] bit and operates with any of the conversion modes and configurations.

## 20.5.1 Clock select and divide control

One of four clock sources can be selected as the clock source for the ADC module. This clock source is then divided by a configurable value to generate the input clock to the converter (ADCK). The clock is selected from one of the following sources by means of the ADC\_SC3[ADICLK] bits.

- The bus clock, which is equal to the frequency at which software is executed. This is the default selection following reset.
- The bus clock divided by 2: For higher bus clock rates, this allows a maximum divide by 16 of the bus clock.
- ALTCLK, that is, alternate clock which is OSCOUT
- The asynchronous clock (ADACK): This clock is generated from a clock source within the ADC module. When selected as the clock source, this clock remains active while the MCU is in Wait or Stop mode and allows conversions in these modes for lower noise operation.

Whichever clock is selected, its frequency must fall within the specified frequency range for ADCK. If the available clocks are too slow, the ADC does not perform according to specifications. If the available clocks are too fast, the clock must be divided to the appropriate frequency. This divider is specified by the ADC\_SC3[ADIV] bits and can be divide-by 1, 2, 4, or 8.

## 20.5.2 Input select and pin control

The Pin Control registers (ADC\_APCTL2 and ADC\_APCTL1) disables the I/O port control of the pins used as analog inputs. When a pin control register bit is set, the following conditions are forced for the associated MCU pin:

- The output buffer is forced to its high impedance state.
- The input buffer is disabled. A read of the I/O port returns a zero for any pin with its input buffer disabled.
- The pullup is disabled.

## 20.5.3 Hardware trigger

The ADC module has a selectable asynchronous hardware conversion trigger, ADHWT, that is enabled when the ADC\_SC2[ADTRG] bit is set. This source is not available on all MCUs. See the module introduction for information on the ADHWT source specific to this MCU.

When ADHWT source is available and hardware trigger is enabled (ADC\_SC2[ADTRG] = 1), a conversion is initiated on the rising edge of ADHWT. If a conversion is in progress when a rising edge occurs, the rising edge is ignored. In continuous convert configuration, only the initial rising edge to launch continuous conversions is observed. The hardware trigger function operates in conjunction with any of the conversion modes and configurations.

## 20.5.4 Conversion control

Conversions can be performed in 10-bit mode, or 8-bit mode as determined by the ADC\_SC3[MODE] bits. Conversions can be initiated by a software or hardware trigger. In addition, the ADC module can be configured for low power operation, long sample time, continuous conversion, and an automatic compare of the conversion result to a software determined compare value.

## 20.5.4.1 Initiating conversions

A conversion initiates under the following conditions:

- A write to ADC\_SC1 or a set of write to ADC\_SC1 in FIFO mode (with ADCH bits not all 1s) if software triggered operation is selected.
- A hardware trigger (ADHWT) event if hardware triggered operation is selected.
- The transfer of the result to the data registers when continuous conversion is enabled.

If continuous conversions are enabled, a new conversion is automatically initiated after the completion of the current conversion. In software triggered operation, continuous conversions begin after ADC\_SC1 is written and continue until aborted. In hardware triggered operation, continuous conversions begin after a hardware trigger event and continue until aborted.

## 20.5.4.2 Completing conversions

A conversion is completed when the result of the conversion is transferred into the data result registers, ADC\_RH and ADC\_RL. This is indicated by the setting of ADC\_SC1[COCO]. An interrupt is generated if ADC\_SC1[AIEN] is high at the time that ADC\_SC1[COCO] is set.

A blocking mechanism prevents a new result from overwriting previous data in ADC\_RH and ADC\_RL if the previous data is in the process of being read while in 10-bit MODE (the ADC\_RH register has been read but the ADC\_RL register has not). When blocking is active, the data transfer is blocked, ADC\_SC1[COCO] is not set, and the new result is lost. In the case of single conversions with the compare function enabled and the compare condition false, blocking has no effect and ADC operation is terminated. In all other cases of operation, when a data transfer is blocked, another conversion is initiated regardless of the state of ADC\_SC1[ADCO] whether single or continuous conversions are enabled.

If single conversions are enabled, the blocking mechanism could result in several discarded conversions and excess power consumption. To avoid this issue, the data registers must not be read after initiating a single conversion until the conversion completes.

In fifo mode, a blocking mechanism will keep current channel conversion and no channel fifo and result fifo switching until a block mechanism is released.

## 20.5.4.3 Aborting conversions

Any conversion in progress is aborted in the following cases:

Functional description

- A write to ADC\_SC1 occurs.
  - The current conversion will be aborted and a new conversion will be initiated, if ADC\_SC1[ADCH] are not all 1s and ADC\_SC4[AFDEP] are all 0s.
  - The current conversion and the rest of conversions will be aborted and no new conversion will be initialed, if ADC\_SC4[AFDEP] are not all 0s.
  - A new conversion will be initiated when the FIFO is re-fulfilled upon the levels indicated by the ADC\_SC4[AFDEP] bits).
- A write to ADC\_SC2, ADC\_SC3, ADC\_SC4, ADC\_CVH, or ADC\_CVL occurs. This indicates a mode of operation change has occurred and the current and rest of conversions (when ADC\_SC4[AFDEP] are not all 0s) are therefore invalid.
- The MCU is reset.
- The MCU enters Stop mode with ADACK not enabled.

When a conversion is aborted, the contents of the data registers, ADC\_RH and ADC\_RL, are not altered. However, they continue to be the values transferred after the completion of the last successful conversion. If the conversion was aborted by a reset, ADC\_RH and ADC\_RL return to their reset states.

### 20.5.4.4 Power control

The ADC module remains in its idle state until a conversion is initiated. If ADACK is selected as the conversion clock source, the ADACK clock generator is also enabled.

Power consumption when active can be reduced by setting ADC\_SC3[ADLPC]. This results in a lower maximum value for  $f_{ADCK}$  (see the data sheet).

### 20.5.4.5 Sample time and total conversion time

The total conversion time depends on the sample time (as determined by ADC\_SC3[ADLSMP]), the MCU bus frequency, the conversion mode (8-bit, 10-bit), and the frequency of the conversion clock ( $f_{ADCK}$ ). After the module becomes active, sampling of the input begins.ADC\_SC3[ADLSMP] selects between short (3.5 ADCK cycles) and long (23.5 ADCK cycles) sample times. When sampling is complete, the converter is isolated from the input channel and a successive approximation algorithm is performed to determine the digital value of the analog signal. The result of the conversion is transferred to ADC\_RH and ADC\_RL upon completion of the conversion algorithm.

If the bus frequency is less than the  $f_{ADCK}$  frequency, precise sample time for continuous conversions cannot be guaranteed when short sample is enabled (ADC\_SC3[ADLSMP] = 0). If the bus frequency is less than 1/11th of the  $f_{ADCK}$  frequency, precise sample time for continuous conversions cannot be guaranteed when long sample is enabled (ADC\_SC3[ADLSMP] = 1).

The maximum total conversion time for different conditions is summarized in the table below.

Conversion type	ADICLK	ADLSMP	Max total conversion time
Single or first continuous 8-bit	0x, 10	0	20 ADCK cycles + 5 bus clock cycles
Single or first continuous 10-bit	0x, 10	0	23 ADCK cycles + 5 bus clock cycles
Single or first continuous 8-bit	0x, 10	1	40 ADCK cycles + 5 bus clock cycles
Single or first continuous 10-bit	0x, 10	1	43 ADCK cycles + 5 bus clock cycles
Single or first continuous 8-bit	11	0	5 µs + 20 ADCK + 5 bus clock cycles
Single or first continuous 10-bit	11	0	5 µs + 23 ADCK + 5 bus clock cycles
Single or first continuous 8-bit	11	1	5 µs + 40 ADCK + 5 bus clock cycles
Single or first continuous 10-bit	11	1	5 µs + 43 ADCK + 5 bus clock cycles
Subsequent continuous 8-bit;	xx	0	17 ADCK cycles
f <sub>BUS</sub> > f <sub>ADCK</sub>			
Subsequent continuous 10-bit;	xx	0	20 ADCK cycles
f <sub>BUS</sub> > f <sub>ADCK</sub>			
Subsequent continuous 8-bit;	xx	1	37 ADCK cycles
f <sub>BUS</sub> > f <sub>ADCK</sub> /11			
Subsequent continuous 10-bit;	xx	1	40 ADCK cycles
f <sub>BUS</sub> > f <sub>ADCK</sub> /11			

Table 20-3. Total conversion time vs. control conditions

The maximum total conversion time is determined by the selected clock source and the divide ratio. The clock source is selectable by the ADC\_SC3[ADICLK] bits, and the divide ratio is specified by the ADC\_SC3[ADIV] bits. For example, in 10-bit mode, with the bus clock selected as the input clock source, the input clock divide-by-1 ratio selected, and a bus frequency of 8 MHz, then the conversion time for a single conversion as given below:

Conversion time = 
$$\frac{23 \text{ ADCK Cyc}}{8 \text{ MHz/1}} + \frac{5 \text{ bus Cyc}}{8 \text{ MHz}} = 3.5 \,\mu\text{s}$$

The number of bus cycles at 8 MHz is:

Bus cycles =  $3.5 \mu s \times 8 M Hz = 28$ 

### Note

The ADCK frequency must be between  $f_{ADCK}$  minimum and  $f_{ADCK}$  maximum to meet ADC specifications.

# 20.5.5 Automatic compare function

The compare function can be configured to check for an upper or lower limit. After the input is sampled and converted, the result is added to the two's complement of the compare value (ADC\_CVH and ADC\_CVL). When comparing to an upper limit (ADC\_SC2[ACFGT] = 1), if the result is greater-than or equal-to the compare value, ADC\_SC1[COCO] is set. When comparing to a lower limit (ADC\_SC2[ACFGT] = 0), if the result is less than the compare value, ADC\_SC1[COCO] is set. The value generated by the addition of the conversion result and the two's complement of the compare value is transferred to ADC\_RH and ADC\_RL.

On completion of a conversion while the compare function is enabled, if the compare condition is not true, ADC\_SC1[COCO] is not set and no data is transferred to the result registers. An ADC interrupt is generated on the setting of ADC\_SC1[COCO] if the ADC interrupt is enabled (ADC\_SC1[AIEN] = 1).

On completion of all conversions while the compare function is enabled and FIFO enabled, if none of the compare conditions are true when ADC\_SC4[ACFSEL] is low or if not all of compare conditions are true when ADC\_SC4[ACFSEL] is high, ADC\_SC1[COCO] is not set. The compare data are transferred to the result registers regardless of compare condition true or false when FIFO enabled.

### Note

The compare function can monitor the voltage on a channel while the MCU is in Wait or Stop mode. The ADC interrupt wakes the MCU when the compare condition is met.

### Note

The compare function can not work in continuous conversion mode when FIFO enabled.

# 20.5.6 FIFO operation

The ADC module supports FIFO operation to minimize the interrupts to CPU in order to reduce CPU loading in ADC interrupt service routines. This module contains two FIFOs to buffer analog input channels and analog results respectively.

The FIFO function is enabled when the ADC\_SC4[AFDEP] bits are set non-zero. The FIFO depth is indicated by these bits. The FIFO supports up to eight level buffer.

The analog input channel FIFO is accessed by ADC\_SC1[ADCH] bits, when FIFO function is enabled. The analog channel must be written to this FIFO in order. The ADC will not start the conversion if the channel FIFO is fulfilled below the level indicated by the ADC\_SC4[AFDEP] bits, no matter whether software or hardware trigger is set. Read ADC\_SC1[ADCH] will read the current active channel value. Write to ADC\_SC1[ADCH] will re-fill channel FIFO to initial new conversion. It will abort current conversion and any other conversions that did not start. Write to the ADC\_SC1 after all the conversions are completed or ADC is in idle state.

The result of the FIFO is accessed by ADC\_RH:ADC\_RL registers, when FIFO function is enabled. The result must be read via these two registers by the same order of analog input channel FIFO to get the proper results. Don't read ADC\_RH:ADC\_RL until all of the conversions are completed in FIFO mode. The ADC\_SC1[COCO] bit will be set only when all conversions indicated by the analog input channel FIFO complete whatever software or hardware trigger is set. An interrupt request will be submitted to CPU if the ADC\_SC1[AIEN] is set when the FIFO conversion completes and the ADC\_SC1[COCO] bit is set.

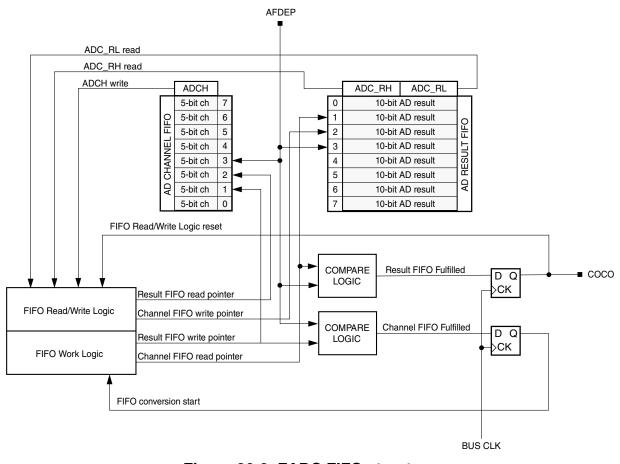

Figure 20-2. FADC FIFO structure

#### Functional description

If software trigger is enabled, the next analog channel is fetched from analog input channel FIFO as soon as a conversion completes and its result is stored in the result FIFO. When all conversions set in the analog input channel FIFO completes, the ADC\_SC1[COCO] bit is set and an interrupt request will be submitted to CPU if the ADC\_SC1[AIEN] bit is set.

If hardware trigger mode is enabled, the next analog is fetched from analog input channel FIFO only when this conversion completes, its result is stored in the result FIFO, and the next hardware trigger is fed to ADC module. When all conversions set in the analog input channel FIFO completes, the ADC\_SC1[COCO] bit is set and an interrupt request will be submitted to CPU if the ADC\_SC1[AIEN] bit is set.

In single conversion in which ADC\_SC1[ADCO] bit is clear, the ADC stops conversions when ADC\_SC1[COCO] bit is set until the channel FIFO is fulfilled again or new hardware trigger occur.

The FIFO also provides scan mode to simplify the dummy work of input channel FIFO. When the ADC\_SC4[ASCANE] bit is set in FIFO mode, the FIFO will always use the first dummied channel in spite of the value in the input channel FIFO. The ADC conversion start to work in FIFO mode as soon as the first channel is dummied. The following write operation to the input channel FIFO will cover the first channel element in this FIFO. In scan FIFO mode, the ADC\_SC1[COCO] bit is set when the result FIFO is fulfilled according to the depth indicated by the ADC\_SC4[AFDEP] bits.

In continuous conversion in which the ADC\_SC1[ADCO] bit is set, the ADC starts next conversion immediately when all conversions are completed. ADC module will fetch the analog input channel from the beginning of analog input channel FIFO.

#### Chapter 20 Analog-to-digital converter (ADC)

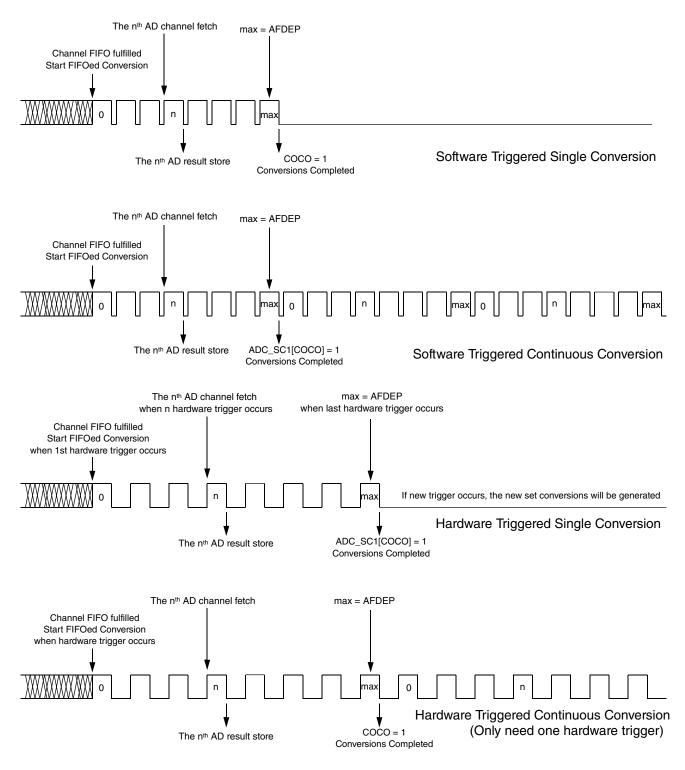

Figure 20-3. ADC FIFO conversion sequence

Functional description

## 20.5.7 MCU wait mode operation

Wait mode is a low-power consumption standby mode from which recovery is fast because the clock sources remain active. If a conversion is in progress when the MCU enters wait mode, it continues until completion. Conversions can be initiated while the MCU is in wait mode by means of the hardware trigger or if continuous conversions are enabled.

The bus clock, bus clock divided by two, ALTCLK and ADACK are available as conversion clock sources while in wait mode.

ADC\_SC1[COCO] is set by a conversion complete event that generates an ADC interrupt to wake the MCU from wait mode if the ADC interrupt is enabled (ADC\_SC1[AIEN] = 1).

## 20.5.8 MCU Stop mode operation

Stop mode is a low-power consumption standby mode during which most or all clock sources on the MCU are disabled.

## 20.5.8.1 Stop mode with ADACK disabled

If the asynchronous clock, ADACK, is not selected as the conversion clock, executing a STOP instruction aborts the current conversion and places the ADC in its idle state. The contents of ADC\_RH and ADC\_RL are unaffected by Stop mode. After exiting from Stop mode, a software or hardware trigger is required to resume conversions.

## 20.5.8.2 Stop mode with ADACK enabled

If ADACK is selected as the conversion clock, the ADC continues operation during Stop mode. For guaranteed ADC operation, the MCU's voltage regulator must remain active during Stop mode. See the module introduction for configuration information for this MCU.

If a conversion is in progress when the MCU enters Stop mode, it continues until completion. Conversions can be initiated while the MCU is in Stop mode by means of the hardware trigger or if continuous conversions are enabled.

A conversion complete event sets the ADC\_SC1[COCO] and generates an ADC interrupt to wake the MCU from Stop mode if the ADC interrupt is enabled (ADC\_SC1[AIEN] = 1). In fifo mode, ADC cannot complete the conversion operation fully or wake the MCU from Stop mode.

#### Note

The ADC module can wake the system from low-power stop and cause the MCU to begin consuming run-level currents without generating a system level interrupt. To prevent this scenario, the data transfer blocking mechanism must be cleared when entering Stop and continuing ADC conversions.

# 20.6 Initialization information

This section gives an example that provides some basic direction on how to initialize and configure the ADC module. You can configure the module for 8-, 10-bit resolution, single or continuous conversion, and a polled or interrupt approach, among many other options. Refer to ADC\_SC3 register for information used in this example.

### Note

Hexadecimal values prefixed by a 0x, binary values prefixed by a %, and decimal values have no preceding character.

## 20.6.1 ADC module initialization example

Before the ADC module can be used to complete conversions, it must be initialized. Given below is a method to initialize ADC module.

## 20.6.1.1 Initialization sequence

A typical initialization sequence is as follows:

- 1. Update the configuration register (ADC\_SC3) to select the input clock source and the divide ratio used to generate the internal clock, ADCK. This register is also used for selecting sample time and low-power configuration.
- 2. Update status and control register 2 (ADC\_SC2) to select the hardware or software conversion trigger and compare function options, if enabled.

#### Initialization information

3. Update status and control register 1 (ADC\_SC1) to select whether conversions will be continuous or completed only once, and to enable or disable conversion complete interrupts. The input channel on which conversions will be performed is also selected here.

### 20.6.1.2 Pseudo-code example

In this example, the ADC module is set up with interrupts enabled to perform a single 10bit conversion at low power with a long sample time on input channel 1, where the internal ADCK clock is derived from the bus clock divided by 1.

### Example: 20.6.1.2.1 General ADC initialization routine

```
void ADC_init(void)
{
    /* The following code segment demonstrates how to initialize ADC by low-power mode,
long
    sample time, bus frequency, software triggered from AD1 external pin without FIF0
enabled
    */
ADC_APCTL1 = ADC_APCTL1_ADPC1_MASK;
ADC_ACSC3 = ADC_SC3_ADLPC_MASK | ADC_SC3_ADLSMP_MASK | ADC_SC3_MODE0_MASK;
ADC_SC2 = 0x00;
ADC_SC1 = ADC_SC1_AIEN_MASK | ADC_SC1_ADCH0_MASK;
}
```

## 20.6.2 ADC FIFO module initialization example

Before the ADC module can be used to start FIFOed conversions, an initialization procedure must be performed. A typical sequence is as follows:

- 1. Update the configuration register (ADC\_SC3) to select the input clock source and the divide ratio used to generate the internal clock, ADCK. This register is also used to select sample time and low-power configuration.
- 2. Update the configuration register (ADC\_SC4) to select the FIFO scan mode, FIFO compare function selection (OR or AND function) and FIFO depth.
- 3. Update status and control register 2 (ADC\_SC2) to select the hardware or software conversion trigger, compare function options if enabled.
- 4. Update status and control register 1 (ADC\_SC1) to select whether conversions will be continuous or completed only once, and to enable or disable conversion complete interrupts. The input channel on which conversions will be performed is also selected here.

### 20.6.2.1 Pseudo-code example

In this example, the ADC module is set up with interrupts enabled to perform a single hardware triggered 10-bit 4-level-FIFO conversion at low power with a long sample time on input channels of 1, 3, 5, and 7. Here the internal ADCK clock is derived from the bus clock divided by 1.

### Example: 20.6.2.1.1 FIFO ADC initialization routine

```
void ADC init (void)
/* The following code segment demonstrates how to initialize ADC by low-power mode, long
sample time, bus frequency, hardware triggered from AD1, AD3, AD5, and AD7 external pins
with 4-level FIFO enabled */
ADC APCTL1 = ADC APCTL1 ADPC6 MASK | ADC APCTL1 ADPC5 MASK | ADC APCTL1 ADPC3 MASK |
ADC APCTL1 ADPC1 MASK; ADC SC3 = ADC SC3 ADLPC MASK | ADC SC3 ADLSMP MASK |
ADC SC3 MODE1 MASK;
// setting hardware trigger
ADC_SC2 = ADC_SC2_ADTRG_MASK ;
//4-Level FIFO
ADC_SC4 = ADC_SC4_AFDEP1_MASK | ADC_SC4_AFDEP0_MASK;
// dummy the 1st channel
ADC SC1 = ADC SC1 ADCH0 MASK;
// dummy the 2nd channel
ADC SC1 = ADC SC1 ADCH1 MASK | ADC SC1 ADCH0 MASK;
// dummy the 3rd channel
ADC SC1 = ADC SC1 ADCH2 MASK | ADC SC1 ADCH0 MASK;
// dummy the 4th channel and ADC starts conversion
ADC_SC1 = ADC_SC1_AIEN_MASK | ADC_SC1_ADCH2_MASK | ADC_SC1_ADCH1_MASK | ADC_SC1_ADCH0_MASK;
}
```

### Example: 20.6.2.1.2 FIFO ADC interrupt service routine

```
unsigned short buffer[4];
interrupt VectorNumber_Vadc void ADC_isr(void)
{
    /* The following code segment demonstrates read AD result FIFO */
    // read conversion result of channel 1 and COCO bit is cleared
    buffer[0] = ADC_R;
    // read conversion result of channel 3
    buffer[1] = ADC_R;
    // read conversion result of channel 5
    buffer[2] = ADC_R;
    // read conversion result of channel 7
    buffer[3] = ADC_R;
}
```

#### NOTE

ADC\_R is 16-bit ADC result register, combined from ADC\_RH and ADC\_RL

# 20.7 Application information

This section contains information for using the ADC module in applications. The ADC has been designed to be integrated into a microcontroller for use in embedded control applications requiring an A/D converter.

# 20.7.1 External pins and routing

The following sections discuss the external pins associated with the ADC module and how they are used for best results.

## 20.7.1.1 Analog supply pins

The ADC module has analog power and ground supplies ( $V_{DDA}$  and  $V_{SSA}$ ) available as separate pins on some devices.  $V_{SSA}$  is shared on the same pin as the MCU digital  $V_{SS}$  on some devices. On other devices,  $V_{SSA}$  and  $V_{DDA}$  are shared with the MCU digital supply pins. In these cases, there are separate pads for the analog supplies bonded to the same pin as the corresponding digital supply so that some degree of isolation between the supplies is maintained.

When available on a separate pin, both  $V_{DDA}$  and  $V_{SSA}$  must be connected to the same voltage potential as their corresponding MCU digital supply ( $V_{DD}$  and  $V_{SS}$ ) and must be routed carefully for maximum noise immunity and bypass capacitors placed as near as possible to the package.

If separate power supplies are used for analog and digital power, the ground connection between these supplies must be at the  $V_{SSA}$  pin. This should be the only ground connection between these supplies if possible. The  $V_{SSA}$  pin makes a good single point ground location.

## 20.7.1.2 Analog reference pins

In addition to the analog supplies, the ADC module has connections for two reference voltage inputs. The high reference is  $V_{REFH}$ , which may be shared on the same pin as  $V_{DDA}$  on some devices. The low reference is  $V_{REFL}$ , which may be shared on the same pin as  $V_{SSA}$  on some devices.

When available on a separate pin,  $V_{REFH}$  may be connected to the same potential as  $V_{DDA}$ , or may be driven by an external source between the minimum  $V_{DDA}$  spec and the  $V_{DDA}$  potential ( $V_{REFH}$  must never exceed  $V_{DDA}$ ). When available on a separate pin,  $V_{REFL}$  must be connected to the same voltage potential as  $V_{SSA}$ .  $V_{REFH}$  and  $V_{REFL}$  must be routed carefully for maximum noise immunity and bypass capacitors placed as near as possible to the package.

AC current in the form of current spikes required to supply charge to the capacitor array at each successive approximation step is drawn through the  $V_{REFH}$  and  $V_{REFL}$  loop. The best external component to meet this current demand is a 0.1 µF capacitor with good high frequency characteristics. This capacitor is connected between  $V_{REFH}$  and  $V_{REFL}$  and must be placed as near as possible to the package pins. Resistance in the path is not recommended because the current causes a voltage drop that could result in conversion errors. Inductance in this path must be minimum (parasitic only).

# 20.7.1.3 Analog input pins

The external analog inputs are typically shared with digital I/O pins on MCU devices. The pin I/O control is disabled by setting the appropriate control bit in one of the pin control registers. Conversions can be performed on inputs without the associated pin control register bit set. It is recommended that the pin control register bit always be set when using a pin as an analog input. This avoids problems with contention because the output buffer is in its high impedance state and the pullup is disabled. Also, the input buffer draws DC current when its input is not at  $V_{DD}$  or  $V_{SS}$ . Setting the pin control register bits for all pins used as analog inputs should be done to achieve lowest operating current.

Empirical data shows that capacitors on the analog inputs improve performance in the presence of noise or when the source impedance is high. Use of 0.01  $\mu$ F capacitors with good high-frequency characteristics is sufficient. These capacitors are not necessary in all cases, but when used they must be placed as near as possible to the package pins and be referenced to V<sub>SSA</sub>.

For proper conversion, the input voltage must fall between  $V_{REFH}$  and  $V_{REFL}$ . If the input is equal to or exceeds  $V_{REFH}$ , the converter circuit converts the signal to 0x3FF (full scale 10-bit representation) or 0xFF (full scale 8-bit representation). If the input is equal to or

#### Application information

less than  $V_{REFL}$ , the converter circuit converts it to 0x000. Input voltages between  $V_{REFH}$  and  $V_{REFL}$  are straight-line linear conversions. There is a brief current associated with  $V_{REFL}$  when the sampling capacitor is charging. The input is sampled for 3.5 cycles of the ADCK source when ADC\_SC3[ADLSMP] is low, or 23.5 cycles when ADC\_SC3[ADLSMP] is high.

For minimal loss of accuracy due to current injection, pins adjacent to the analog input pins should not be transitioning during conversions.

## 20.7.2 Sources of error

Several sources of error exist for A/D conversions. These are discussed in the following sections.

## 20.7.2.1 Sampling error

For proper conversions, the input must be sampled long enough to achieve the proper accuracy. Given the maximum input resistance of approximately 7 k $\Omega$  and input capacitance of approximately 5.5 pF, sampling to within 1/4 LSB can be achieved within the minimum sample window (3.5 cycles at 8 MHz maximum ADCK frequency) provided the resistance of the external analog source (R<sub>AS</sub>) is kept below 2 k $\Omega$ .

Higher source resistances or higher-accuracy sampling is possible by setting ADC\_SC3[ADLSMP] (to increase the sample window to 23.5 cycles) or decreasing ADCK frequency to increase sample time.

### 20.7.2.2 Pin leakage error

Leakage on the I/O pins can cause conversion error if the external analog source resistance ( $R_{AS}$ ) is high. If this error cannot be tolerated by the application, keep  $R_{AS}$  lower than  $V_{DDA}$  / ( $2^{N*}I_{LEAK}$ ) for less than 1/4 LSB leakage error (N = 8 in 8-bit, 10 in 10-bit).

### 20.7.2.3 Noise-induced errors

System noise that occurs during the sample or conversion process can affect the accuracy of the conversion. The ADC accuracy numbers are guaranteed as specified only if the following conditions are met:

- There is a 0.1  $\mu$ F low-ESR capacitor from V<sub>REFH</sub> to V<sub>REFL</sub>.
- There is a 0.1  $\mu$ F low-ESR capacitor from V<sub>DDA</sub> to V<sub>SSA</sub>.
- If inductive isolation is used from the primary supply, an additional 1  $\mu$ F capacitor is placed from V<sub>DDA</sub> to V<sub>SSA</sub>.
- $V_{SSA}$  (and  $V_{REFL}$ , if connected) is connected to  $V_{SS}$  at a quiet point in the ground plane.
- Operate the MCU in wait or Stop mode before initiating (hardware triggered conversions) or immediately after initiating (hardware or software triggered conversions) the ADC conversion.
  - For software triggered conversions, immediately follow the write to ADC\_SC1 with a wait instruction or stop instruction.
  - For Stop mode operation, select ADACK as the clock source. Operation in Stop reduces  $V_{DD}$  noise but increases effective conversion time due to stop recovery.
- There is no I/O switching, input or output, on the MCU during the conversion.

There are some situations where external system activity causes radiated or conducted noise emissions or excessive  $V_{DD}$  noise is coupled into the ADC. In these situations, or when the MCU cannot be placed in wait or Stop or I/O activity cannot be halted, these recommended actions may reduce the effect of noise on the accuracy:

- Place a 0.01  $\mu$ F capacitor (C<sub>AS</sub>) on the selected input channel to V<sub>REFL</sub> or V<sub>SSA</sub> (this improves noise issues, but affects the sample rate based on the external analog source resistance).
- Average the result by converting the analog input many times in succession and dividing the sum of the results. Four samples are required to eliminate the effect of a 1LSB, one-time error.
- Reduce the effect of synchronous noise by operating off the asynchronous clock (ADACK) and averaging. Noise that is synchronous to ADCK cannot be averaged out.

### 20.7.2.4 Code width and quantization error

The ADC quantizes the ideal straight-line transfer function into 1024 steps (in 10-bit mode). Each step ideally has the same height (1 code) and width. The width is defined as the delta between the transition points to one code and the next. The ideal code width for an N bit converter (in this case N can be 8, 10), defined as 1LSB, is:

 $1 \, \text{lsb} = \left( V_{\text{REFH}} - V_{\text{REFL}} \right) / 2^N$ 

There is an inherent quantization error due to the digitization of the result. For 8-bit or 10-bit conversions the code transitions when the voltage is at the midpoint between the points where the straight line transfer function is exactly represented by the actual transfer function. Therefore, the quantization error will be  $\pm 1/2$  lsb in 8- or 10-bit mode. As a consequence, however, the code width of the first (0x000) conversion is only 1/2 lsb and the code width of the last (0xFF or 0x3FF) is 1.5 lsb.

## 20.7.2.5 Linearity errors

The ADC may also exhibit non-linearity of several forms. Every effort has been made to reduce these errors but the system must be aware of them because they affect overall accuracy. These errors are:

- Zero-scale error (E<sub>ZS</sub>) (sometimes called offset) This error is defined as the difference between the actual code width of the first conversion and the ideal code width (1/2 lsb in 8-bit or 10-bit modes). If the first conversion is 0x001, the difference between the actual 0x001 code width and its ideal is used.
- Full-scale error  $(E_{FS})$  This error is defined as the difference between the actual code width of the last conversion and the ideal code width (1.5 lsb in 8-bit or 10-bit modes). If the last conversion is 0x3FE, the difference between the actual 0x3FE code width and its ideal is used.
- Differential non-linearity (DNL) This error is defined as the worst-case difference between the actual code width and the ideal code width for all conversions.
- Integral non-linearity (INL) This error is defined as the highest-value that the absolute value of the running sum of DNL achieves. More simply, this is the worst-case difference of the actual transition voltage to a given code and its corresponding ideal transition voltage, for all codes.
- Total unadjusted error (TUE) This error is defined as the difference between the actual transfer function and the ideal straight-line transfer function and includes all forms of error.

## 20.7.2.6 Code jitter, non-monotonicity, and missing codes

Analog-to-digital converters are susceptible to three special forms of error. These are code jitter, non-monotonicity, and missing codes.

Code jitter occurs when, at certain points, a given input voltage converts to one of two values when sampled repeatedly. Ideally, when the input voltage is infinitesimally smaller than the transition voltage, the converter yields the lower code (and vice-versa). However, even small amounts of system noise can cause the converter to be indeterminate, between two codes, for a range of input voltages around the transition voltage. This range is normally around  $\pm 1/2$  lsb in 8-bit or 10-bit mode, and increases with noise.

This error may be reduced by repeatedly sampling the input and averaging the result. Additionally the techniques discussed in Noise-induced errors reduces this error.

Non-monotonicity is defined when, except for code jitter, the converter converts to a lower code for a higher input voltage. Missing codes are those values that are never converted for any input value.

In 8-bit or 10-bit mode, the ADC is guaranteed to be monotonic and have no missing codes.

# Chapter 21 Analog comparator (ACMP)

# 21.1 Chip specific ACMP information

This device includes one analog comparator module. The following table summarizes the external signals of ACMP modules

ACMP	Channel	Connection
ACMP0	0	PTA0/ACMP0IN0
	1	PTA1/ACMP0IN1
	2	Reserved
	3	DAC output
	Output	PTA4/ACMP0O

Table 21-1. ACMP modules external signals

## 21.1.1 ACMP configuration information

Each ACMP contains one 6-bit DAC. Besides internal DAC reference, ACMP supports choosing external reference. When using the bandgap reference voltage as the reference voltage to the built-in DAC, the user must enable the bandgap buffer by setting SPMSC1[BGBE] = 1.

## 21.1.2 ACMP in Stop3 mode

This module continues to operate in stop3 mode if enabled. The MCU is brought out of stop when a compare event occurs and ACIE is enabled; ACF flag sets accordingly.

# 21.1.3 ACMP0 for SCI0 RXD Filter

SCI0 RxD input can be filtered by ACMP0 module. Refer to Figure 7-1.

## 21.1.4 ACMP0 output as FTM2CH0 input capture

ACMP0 output can be FTM2CH0 input capture source. Refer to Figure 7-1.

## 21.1.5 ACMP0 for ADC trigger

ACMP0 output can be ADC trigger source. Refer to Figure 7-1.

# 21.2 Introduction

The analog comparator module (ACMP) provides a circuit for comparing two analog input voltages. The comparator circuit is designed to operate across the full range of the supply voltage (rail-to-rail operation).

The analog mux provides a circuit for selecting an analog input signal from eight channels. One signal provided by the 6-bit DAC. The mux circuit is designed to operate across the full range of the supply voltage. The 6-bit DAC is 64-tap resistor ladder network which provides a selectable voltage reference for applications where voltage reference is needed. The 64-tap resistor ladder network divides the supply reference  $V_{in}$  into 64 voltage level. A 6-bit digital signal input selects output voltage level, which varies from  $V_{in}$  to  $V_{in}/64$ .  $V_{in}$  can be selected from two voltage sources.

## 21.2.1 Features

ACMP features include:

- Operational over the whole supply range of 2.7 V to 5.5 V
- On-chip 6-bit resolution DAC with selectable reference voltage from  $V_{DD}$  or internal bandgap
- Configurable hysteresis
- Selectable interrupt on rising edge, falling edge, or both rising or falling edges of comparator output
- Selectable inversion on comparator output
- Up to four selectable comparator inputs
- Operational in Stop mode

## 21.2.2 Modes of operation

This section defines the ACMP operation in Wait, Stop, and Background Debug modes.

## 21.2.2.1 Operation in Wait mode

The ACMP continues to operate in Wait mode, if enabled. The interrupt can wake the MCU if enabled.

## 21.2.2.2 Operation in Stop mode

The ACMP (including DAC and CMP) continues to operate in Stop mode if enabled. If ACMP\_CS[ACIE] is set, a ACMP interrupt can be generated to wake the MCU up from Stop mode.

If the Stop is exited by an interrupt, the ACMP setting remains before entering the Stop mode. If Stop is exited with a reset, the ACMP goes into its reset.

The user must turn off the DAC if the output is not used as a reference input of ACMP to save power, because the DAC consumes additional power.

## 21.2.2.3 Operation in Debug mode

When the MCU is in Debug mode, the ACMP continues operating normally.

## 21.2.3 Block diagram

The block diagram of the ACMP module is shown in the following figure.

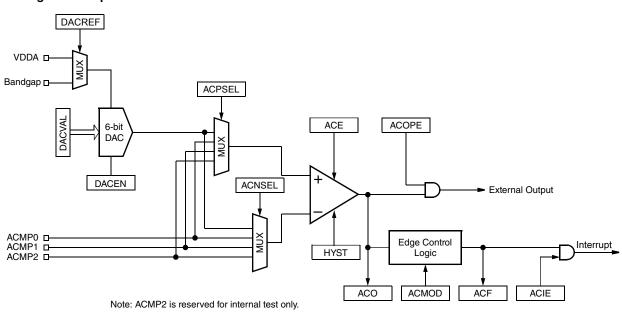

Figure 21-1. ACMP block diagram

## 21.3 External signal description

The output of ACMP can also be mapped to an external pin. When the output is mapped to an external pin, ACMP\_CS[ACOPE] controls the pin to enable/disable the ACMP output function.

# 21.4 Memory map and register definition

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
2C	ACMP Control and Status Register (ACMP0_CS)	8	R/W	00h	21.4.1/365

Reset	0	0	0	0	0	0	0	0

### ACMPx\_CS field descriptions

Field	Description
7 ACE	Analog Comparator Enable
102	Enables the ACMP module.
	0 The ACMP is disabled.
	1 The ACMP is enabled.
6 HYST	Analog Comparator Hysterisis Selection
	Selects ACMP hysterisis.
	0 20 mV.
	1 30 mV.
5 ACF	ACMP Interrupt Flag Bit
	Synchronously set by hardware when ACMP output has a valid edge defined by ACMOD. The setting of this bit lags the ACMPO to bus clocks. Clear ACF bit by writing a 0 to this bit. Writing a 1 to this bit has n effect.
4	ACMP Interrupt Enable
ACIE	Enables an ACMP CPU interrupt.
	0 Disable the ACMP Interrupt.
	1 Enable the ACMP Interrupt.
3	ACMP Output
ACO	Reading ACO will return the current value of the analog comparator output. ACO is reset to a 0 and will read as a 0 when the ACMP is disabled (ACE = $0$ )
2	ACMP Output Pin Enable
ACOPE	ACOPE enables the pad logic so that the output can be placed onto an external pin.
	0 ACMP output cannot be placed onto external pin.
	1 ACMP output can be placed onto external pin.
ACMOD	ACMP MOD
	Determines the sensitivity modes of the interrupt trigger.
	00 ACMP interrupt on output falling edge.
	01 ACMP interrupt on output rising edge.
	01 ACMP interrupt on output rising edge.

Table continues on the next page ...

## 21.4.3 ACMP Control Register 1 (ACMPx\_C1)

Field	Description
7	DAC Enable
DACEN	Enables the output of 6-bit DAC.
	0 The DAC is disabled.
	1 The DAC is enabled.
6 DACREF	DAC Reference Select
	0 The DAC selects Bandgap as the reference.
	1 The DAC selects $V_{DDA}$ as the reference.
DACVAL	DAC Output Level Selection
	Selects the output voltage using the given formula: $V_{output} = (V_{in}/64)x(DACVAL[5:0]+1)$ The $V_{output}$ range is from $V_{in}/64$ to $V_{in}$ , the step is $V_{in}/64$

### ACMPx\_C1 field descriptions

## 21.4.4 ACMP Control Register 2 (ACMPx\_C2)

Address: 2Ch base + 3h offset = 2Fh

### ACMPx\_C2 field descriptions

Field	Description
7–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
ACIPE	ACMP Input Pin Enable This 2-bit field controls if the corresponding ACMP external pin can be driven by an analog input.
	<ul><li>0 The corresponding external analog input is not allowed.</li><li>1 The corresponding external analog input is allowed.</li></ul>

## 21.5 Functional description

The ACMP module is functionally composed of two parts: digital-to-analog (DAC) and comparator (CMP).

### Setup and operation of ACMP

The DAC includes a 64-level DAC (digital to analog converter) and relevant control logic. DAC can select one of two reference inputs,  $V_{DD}$  or on-chip bandgap, as the DAC input  $V_{in}$  by setting ACMP\_C1[DACREF]. After the DAC is enabled, it converts the data set in ACMP\_C1[DACVAL] to a stepped analog output, which is fed into ACMP as an internal reference input. This stepped analog output is also mapped out of the module. The output voltage range is from  $V_{in}/64$  to  $V_{in}$ . The step size is  $V_{in}/64$ .

The ACMP can achieve the analog comparison between positive input and negative input, and then give out a digital output and relevant interrupt. Both the positive and negative input of ACMP can be selected from the four common inputs: three external reference inputs and one internal reference input from the DAC output. The positive input of ACMP is selected by ACMP\_C0[ACPSEL] and the negative input is selected by ACMP\_C0[ACNSEL]. Any pair of the eight inputs can be compared by configuring the ACMPC0 with the appropriate value.

After the ACMP is enabled by setting ACMP\_CS[ACE], the comparison result appears as a digital output. Whenever a valid edge defined in ACMP\_CS[ACMOD] occurs, ACMP\_CS[ACF] is asserted. If ACMP\_CS[ACIE] is set, a ACMP CPU interrupt occurs. The valid edge is defined by ACMP\_CS[ACMOD]. When ACMP\_CS[ACMOD] = 00b or 10b, only the falling-edge on ACMP output is valid. When ACMP\_CS[ACMOD] = 01b, only rising-edge on ACMP output is valid. When ACMP\_CS[ACMOD] = 11b, both the rising-edge and falling-edge on the ACMP output are valid.

The ACMP output is synchronized by the bus clock to generate ACMP\_CS[ACO] so that the CPU can read the comparison. In stop3 mode, if the output of ACMP is changed, ACMPO cannot be updated in time. The output can be synchronized and ACMP\_CS[ACO] can be updated upon the waking up of the CPU because of the availability of the bus clock. ACMP\_CS[ACO] changes following the comparison result, so it can serve as a tracking flag that continuously indicates the voltage delta on the inputs.

If a reference input external to the chip is selected as an input of ACMP, the corresponding ACMP\_C2[ACIPE] bit must be set to enable the input from pad interface. If the output of the ACMP needs to be put onto the external pin, the ACMP\_CS[ACOPE] bit must enable the ACMP pin function of pad logic.

# 21.6 Setup and operation of ACMP

The two parts of ACMP (DAC and CMP) can be set up and operated independently. But if the DAC works as an input of the CMP, the DAC must be configured before the ACMP is enabled.

Because the input-switching can cause problems on the ACMP inputs, the user should complete the input selection before enabling the ACMP and must not change the input selection setting when the ACMP is enabled to avoid unexpected output. Similarly, because the DAC experiences a setup delay after ACMP\_C1[DACVAL] is changed, the user should complete the setting of ACMP\_C1[DACVAL] before DAC is enabled.

# 21.7 Resets

During a reset the ACMP is configured in the default mode. Both CMP and DAC are disabled.

# 21.8 Interrupts

If the bus clock is available when a valid edge defined in ACMP\_CS[ACMOD] occurs, the ACMP\_CS[ACF] is asserted. If ACMP\_CS[ACIE] is set, a ACMP interrupt event occurs. The ACMP\_CS[ACF] bit remains asserted until the ACMP interrupt is cleared by software. When in stop3 mode, a valid edge on ACMP output generates an asynchronous interrupt that can wake the MCU from stop3. The interrupt can be cleared by writing a 0 to the ACMP\_CS[ACF] bit.

# Chapter 22 Cyclic redundancy check (CRC)

# 22.1 Introduction

Cyclic redundancy check (CRC) generates 16/32-bit CRC code for error detection. The CRC can be configured to work as a standard CRC. It provides the user with programmable polynomial, SEED and other parameters required to implement a 16-bit or 32-bit CRC standard. These parameters are detailed in further sections.

## 22.2 Features

Features of the CRC module are:

- Hardware 16/32-bit CRC generator
- Programmable initial seed value
- Programmable 16/32-bit polynomial
- Optional feature to reverse input and output data by bit
- Optional final complement output of result
- High-speed CRC calculation

# 22.3 Block diagram

The following figure is the CRC block diagram.

Modes of operation

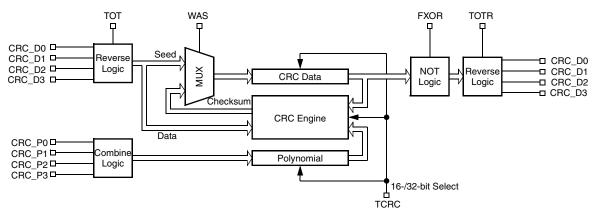

Figure 22-1. Cyclic redundancy check (S08CRC) block diagram

## 22.4 Modes of operation

This section defines the CRC operation in run, wait, and stop modes.

- Run mode This is the basic mode of operation in which CRC is full functional.
- Wait mode The CRC module is optional functional
- Stop3 mode The CRC module is not functional in this low-power standby state. CRC calculations in progress stop and will resume after the CPU goes into run mode.

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
3060	CRC Data 0 Register (CRC_D0)	8	R/W	FFh	22.5.1/373
3061	CRC Data 1 Register (CRC_D1)	8	R/W	FFh	22.5.2/373

## 22.5 Register definition

### **CRC** memory map

## 22.5.1 CRC Data 0 Register (CRC\_D0)

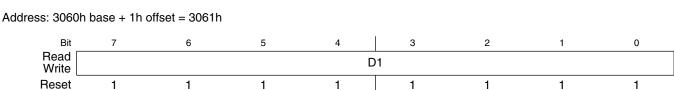

D0 is one of the CRC data registers (D0:D3). The set of CRC data registers contains the value of seed, data, and checksum. When CRC\_CTRL[WAS] bit is set, any write to the data registers is regarded as seed for CRC module. When CRC\_CTRL[WAS] bit is clear, any write to the data registers is regarded as data for general CRC computation, in which D0:D2 does not accept any data and D3 accept 8-bit write upon the polynomial configuration. When final data are written, the final result can be read from the data register. The registers of D0:D1 contain the MSB 16-bit of CRC data, which is used only in CRC 32-bit mode. Only D3 is used to dummy data to CRC. Writing D2 will be ignored when WAS = 0.

Address: 3060h base + 0h offset = 3060h

## 22.5.2 CRC Data 1 Register (CRC\_D1)

D1 is one of the CRC data registers (D0:D3). The set of CRC data registers contains the value of seed, data, and checksum. When CRC\_CTRL[WAS] bit is set, any write to the data registers is regarded as seed for CRC module. When CRC\_CTRL[WAS] bit is clear, any write to the data registers is regarded as data for general CRC computation, in which D0:D2 does not accept any data and D3 accept 8-bit write upon the polynomial configuration. When final data are written, the final result can be read from the data register. The registers of D0:D1 contain the MSB 16-bit of CRC data, which is used only in CRC 32-bit mode. Only D3 is used to dummy data to CRC. Writing D2 will be ignored when WAS = 0.

MC9S08PL16S Reference Manual, Rev. 3, 06/2020

CRC\_D3 field descriptions

Field	Description
D3	CRC Data Bit 7:0

## 22.5.5 CRC Polynomial 0 Register (CRC\_P0)

P0 is one of the CRC polynomial registers (P0:P3). The set of CRC polynominal registers contains the value of polynomial. The registers of P0:P1 contain the MSB 16-bit of CRC polynomial, which is used only in CRC 32-bit mode. The registers of P2:P3 contain the LSB 16-bit of CRC polynomial, which is used in both CRC 16- and 32-bit modes.

Address: 3060h base + 4h offset = 3064h

Field	Description			
P0	CRC Polynominal Bit 31:24			

## 22.5.6 CRC Polynomial 1 Register (CRC\_P1)

P1 is one of the CRC polynomial registers (P0:P3). The set of CRC polynominal registers contains the value of polynomial. The registers of P0:P1 contain the MSB 16-bit of CRC polynomial, which is used only in CRC 32-bit mode. The registers of P2:P3 contain the LSB 16-bit of CRC polynomial, which is used in both CRC 16- and 32-bit modes.

### CRC\_CTRL field descriptions (continued)

## 22.6 Functional description

## 22.6.1 16-bit CRC calculation

The following steps show how to start a general 16-bit CRC calculation:

- 1. Clear CRC\_CTRL[TCRC] bit to enable 16-bit CRC mode.
- 2. Optional to enable reverse and complement function. Please see Bit reverse and Result complement for details.
- 3. Write 16-bit polynomial to CRC\_P2:CRC\_P3.
- 4. Set CRC\_CTRL[WAS] bit to allow CRC\_D2:CRC\_D3 to be written by seed.
- 5. Write 16-bit seed to CRC\_D2:CRC\_D3.
- 6. Clear CRC\_CTRL[WAS] bit to start 16-bit CRC calculation.
- 7. Dummy CRC\_D3 with 8-bit CRC raw data.
- 8. Get the checksum from CRC\_D2:CRC\_D3 when all CRC raw data dummied.

## 22.6.2 32-bit CRC calculation

The following steps show how to start a general 32-bit CRC calculation:

1. Set CRC\_CTRL[TCRC] bit to enable 32-bit CRC mode.

- 2. Optional to enable reverse and complement function. Please see Bit reverse and Result complement for details.
- 3. Write 32-bit polynomial to CRC\_P0:CRC\_P3.
- 4. Set CRC\_CTRL[WAS] bit to allow CRC\_D0:CRC\_D3 written by seed.
- 5. Write 32-bit seed to CRC\_D0:CRC\_D3.
- 6. Clear CRC\_CTRL[WAS] bit to start 32-bit CRC calculation.
- 7. Dummy CRC\_D3 with 8-bit CRC raw data.
- 8. Get the checksum from CRC\_D0:CRC\_D3 when all CRC raw data dummied.

## 22.6.3 Bit reverse

The bit reverse function allows the input and output data reversed by bit for different CRC standard and endian systems. The CRC\_CTRL[TOT] bits control the reverse of input data and the CRC\_CTRL[TOTR] bits control the reverse of output data. The following table shows how the CRC\_CTRL[TOT] and CRC\_CTRL[TOTR] bits work.

 Table 22-1.
 TOT and TOTR bit and byte reverse function

TOT ROW	D0	D1	D2	D3
00	b31b30b29b28b27b26b 25b24	b23b22b21b20b19b18b 17b16	b15b14b13b12b11b10b 9b8	b7b6b5b4b3b2b1b0
01	b24b25b26b27b28b29b 30b31	b16b17b18b19b20b21b 22b23	b8b9b10b11b12b13b14 b15	b0b1b2b3b4b5b6b7

### NOTE

00 is the default case that no bit is reversed.

## 22.6.4 Result complement

The result complement function allows to output the complement of the checksum in CRC data registers. When CRC\_CTRL[FXOR] bit is set, the checksum is read by its complement. Otherwise, the raw checksum is accessed.

## 22.6.5 CCITT compliant CRC example

The following code segment shows CCITT CRC-16 compliant example.

### Example: 22.6.5.1 CCITT CRC-16 compliant example

#### **Functional description**

```
CRC_CTRL = CRC_CTRL_WAS_MASK; // 16-bit CRC, ready to dummy seed
CRC_P2P3 = 0x1021; // Standard CCITT polynomail of (x^16 + x^12 + x^5 + 1)
CRC_D2D3 = 0xFFFF; // Set seed by 0xFFFF
CRC_CTRL = 0x00;
for ( i = 0 ; i < 128 ; i++ )
{
CRC_D3 = 'A'; // Dummy 256 'A'
CRC_D3 = 'A';
}
// Get 0xea0b in CRC_D2:CRC_D3 here
```

# Chapter 23 Windowed COP (WCOP)

# 23.1 Chip specific WCOP information

This device includes one windowed COP (WCOP) which has four clock options:

WCOP Module Clock Interface	Chip Specific Clock Source
Bus clock (BUSCLK)	BUSCLK
Internal LPO clock (LPOCLK)	LPOCLK (1 kHz)
Internal RC oscillator clock (IRCLK)	ICSIRCLK (up to the 32 kHz)
External clock (EXTCLK)	OSCOUT

 Table 23-1.
 WCOP clock options

The WCOP control and status registers are implemented in SYS\_SOPT5.

# 23.2 Introduction

The Windowed COP (WCOP) module is an independent timer that is available for system use. It provides a safety feature to ensure that software is executing as planned and the CPU is not stuck in an infinite loop or executing unintended code. If the WCOP counter is not reset (refreshed) within a certain period, it resets the MCU.

# 23.3 Features

The WCOP has the following features:

- Configurable clock source inputs independent from the:
  - Bus clock (BUSCLK)
  - Internal LPO clock (LPOCLK)

### Functional description

- Internal RC oscillator clock (IRCLK)
- External clock (EXTCLK)
- Programmable timeout period based on different clock source:
  - $2^5$ ,  $2^8$  or  $2^{10}$  cycles (LPOCLK or IRCLK)
  - $2^{13}$ ,  $2^{16}$  or  $2^{18}$  cycles (BUSCLK or EXTCLK)
- Robust write sequence for counter refresh
  - Refresh sequence of writing 0x55 and then 0xAA to the address of SRS during the selected timeout period
- Window mode option for the refresh mechanism
  - Provides robust check that program flow is faster than expected
  - Early refresh attempts trigger a reset
- Optional timeout interrupt to allow post-processing diagnostics
  - Interrupt request to CPU with interrupt vector for an interrupt service routine (ISR)
- Configuration bits are write-once-after-reset to ensure watchdog configuration cannot be mistakenly altered

# 23.4 Functional description

The Windowed Computer operating properly (WCOP) watchdog is used to force a system reset when the application software fails to execute as expected. To prevent a system reset from the WCOP timer (when it is enabled), application software must reset (refresh) the WCOP counter periodically. If the application program gets lost and fails to reset the WCOP counter before it times out, a system reset is generated to force the system back to an known starting point. After any reset, the WCOP watchdog is enabled (see SYS\_SOPT5 for additional information). If the WCOP watchdog is not used in an application, it can be disabled by clearing SYS\_SOPT5[COPT].

## 23.4.1 Watchdog refresh mechanism

The WCOP counter is reset (refreshed) by writing 0x55 and 0xAA (in this order) to the address of SRS during the selected timeout period. Writes do not affect the data in the read-only SRS. As soon as the write sequence is done, the WCOP timeout period is restarted. If the program fails to do this during the time-out period, the MCU will reset. Also, if any value other than 0x55 or 0xAA is written to SRS, the MCU is immediately reset.

This will prevent accidental changes if the application program gets lost. The write to SRS that services (refreshed) the WCOP counter must not be placed in an interrupt service routine (ISR) because the ISR could continue to be executed periodically even if the main application program fails.

## 23.4.2 Window mode

When the bus clock source is selected, windowed COP operation is available by setting SYS\_SOPT5[COPW]. In this mode, writes to the SRS register to clear the WCOP timer must occur in the last 25% of the selected timeout period. A premature write immediately resets the MCU. When the LPO, IRCLK, or EXTCLK clock source is selected, windowed COP operation is not available.

# 23.5 Configuring the WCOP

All watchdog control bits are write-once after reset. This means that after a write has occurred they cannot be changed unless a reset occurs. This provides a robust mechanism to configure the watchdog and ensure that a runaway condition cannot mistakenly disable or modify the watchdog configuration after configured.

The WCOP counter is initialized by the first writes to the SYS\_SOPT5[COPCLKS] and after any system reset. Subsequent writes to SYS\_SOPT5 have no effect on COP operation. Even if the application will use the reset default settings of SYS\_SOPT5[COPT], SYS\_SOPT5[COPCLKS], and SYS\_SOPT5[COPW] bits, the user must write to the write-once SYS\_SOPT5 register during reset initialization to lock in the settings.

# 23.6 Clock source

The SYS\_SOPT5[COPCLKS] selects the clock source used for the WCOP timer. The clock source options are:

- Bus clock (BUSCLK)
- Internal LPO clock (LPOCLK)
- Internal RC oscillator clock (IRCLK)
- External clock (EXTCLK)

#### Functionality in debug and low-power modes

With each clock source, there are three associated time-outs controlled by SYS\_SOPT5[COPT]. The following table summarizes the control functions of the SYS\_SOPT5[COPCLKS] and SYS\_SOPT5[COPT] bits. The WCOP watchdog defaults to operation from the LPO clock source and the longest time-out (2<sup>10</sup> cycles)

Control bits		Clock source	WCOP window	WCOP timeout period
SYS_SOPT5[COPCLK S]	SYS_SOPT5[COPT]		opens <sup>1</sup>	
N/A	00	N/A	N/A	WCOP is disabled
00/10	01	LPOCLK/IRCLK	N/A	2 <sup>5</sup> cycles
00/10	10	LPOCLK/IRCLK	N/A	2 <sup>8</sup> cycles
00/10	11	LPOCLK/IRCLK	N/A	2 <sup>10</sup> cycles
01	01	BUSCLK	6,144 cycles	2 <sup>13</sup> cycles
01	10	BUSCLK	49,152 cycles	2 <sup>16</sup> cycles
01	11	BUSCLK	196,608 cycles	2 <sup>18</sup> cycles
11	01	EXTCLK	N/A	2 <sup>13</sup> cycles
11	10	EXTCLK	N/A	2 <sup>16</sup> cycles
11	11	EXTCLK	N/A	2 <sup>18</sup> cycles

 Table 23-2.
 Configuration option

Windowed COP operation requires the user to clear the WCOP timer in the last 25% of the selected timeout period. This
column displays the minimum number of clock counts required before the WCOP timer can be reset when in windowed
COP mode (SYS\_SOPT5[COPW] = 1).

## 23.7 Functionality in debug and low-power modes

If the bus clock source is selected, the WCOP counter does not increment while the MCU is in background debug mode or while the system is in stop mode. The WCOP counter resumes when the MCU exits background debug mode or stop mode.

If the LPO, IRCLK, or EXTCLK clock source is selected, the WCOP counter is reinitialized to zero upon entry to either background debug mode or stop mode and begins from zero upon exit from background debug mode or stop mode.

# Chapter 24 Development support

## 24.1 Introduction

This chapter describes the single-wire background debug mode (BDM), which uses the on-chip background debug controller (BDC) module, and the independent on-chip real-time in-circuit emulation (ICE) system, which uses the on-chip debug (DBG) module.

## 24.1.1 Forcing active background

The method for forcing active background mode depends on the specific HCS08 derivative. For the 9S08xxxx, you can force active background after a power-on reset by holding the BKGD pin low as the device exits the reset condition. You can also force active background by driving BKGD low immediately after a serial background command that writes a one to the BDFR bit in the SBDFR register. Other causes of reset including an external pin reset or an internally generated error reset ignore the state of the BKGD pin and reset into normal user mode. If no debug pod is connected to the BKGD pin, the MCU will always reset into normal operating mode.

## 24.1.2 Features

Features of the BDC module include:

- Single pin for mode selection and background communications
- BDC registers are not located in the memory map
- SYNC command to determine target communications rate
- Non-intrusive commands for memory access
- Active background mode commands for CPU register access
- GO and TRACE1 commands
- BACKGROUND command can wake CPU from stop or wait modes
- One hardware address breakpoint built into BDC

MC9S08PL16S Reference Manual, Rev. 3, 06/2020

### Background debug controller (BDC)

- BDC clock runs in stop mode, if BDC enabled
- Watchdog disabled by default while in active background mode. It can also be enabled by proper configuration

Features of the ICE system include:

- Two trigger comparators: Two address + read/write (R/W) or one full address + data + R/W
- Flexible 8-word by 16-bit FIFO (first-in, first-out) buffer for capture information:
  - Change-of-flow addresses or
  - Event-only data
- Two types of breakpoints:
  - Tag breakpoints for instruction opcodes
  - Force breakpoints for any address access
- Nine trigger modes:
  - Basic: A-only, A OR B
  - Sequence: A then B
  - Full: A AND B data, A AND NOT B data
  - Event (store data): Event-only B, A then event-only B
  - Range: Inside range (A ≤ address ≤ B), outside range (address < A or address > B)

# 24.2 Background debug controller (BDC)

All MCUs in the HCS08 Family contain a single-wire background debug interface that supports in-circuit programming of on-chip nonvolatile memory and sophisticated non-intrusive debug capabilities. Unlike debug interfaces on earlier 8-bit MCUs, this system does not interfere with normal application resources. It does not use any user memory or locations in the memory map and does not share any on-chip peripherals.

BDC commands are divided into two groups:

- Active background mode commands require that the target MCU is in active background mode (the user program is not running). Active background mode commands allow the CPU registers to be read or written, and allow the user to trace one user instruction at a time, or GO to the user program from active background mode.
- Non-intrusive commands can be executed at any time even while the user's program is running. Non-intrusive commands allow a user to read or write MCU memory locations or access status and control registers within the background debug controller.

Typically, a relatively simple interface pod is used to translate commands from a host computer into commands for the custom serial interface to the single-wire background debug system. Depending on the development tool vendor, this interface pod may use a standard RS-232 serial port, a parallel printer port, or some other type of communications such as a universal serial bus (USB) to communicate between the host PC and the pod. The pod typically connects to the target system with ground, the BKGD pin, RESET, and sometimes  $V_{DD}$ . An open-drain connection to reset allows the host to force a target system reset, which is useful to regain control of a lost target system or to control startup of a target system before the on-chip nonvolatile memory has been programmed. Sometimes  $V_{DD}$  can be used to allow the pod to use power from the target system to avoid the need for a separate power supply. However, if the pod is powered separately, it can be connected to a running target system without forcing a target system reset or otherwise disturbing the running application program.

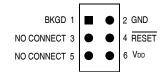

Figure 24-1. BDM tool connector

# 24.2.1 BKGD pin description

BKGD is the single-wire background debug interface pin. The primary function of this pin is for bidirectional serial communication of active background mode commands and data. During reset, this pin is used to select between starting in active background mode or starting the user's application program. This pin is also used to request a timed sync response pulse to allow a host development tool to determine the correct clock frequency for background debug serial communications.

BDC serial communications use a custom serial protocol first introduced on the M68HC12 Family of microcontrollers. This protocol assumes the host knows the communication clock rate that is determined by the target BDC clock rate. All communication is initiated and controlled by the host that drives a high-to-low edge to signal the beginning of each bit time. Commands and data are sent most significant bit first (MSB first). For a detailed description of the communications protocol, refer to Communication details.

If a host is attempting to communicate with a target MCU that has an unknown BDC clock rate, a SYNC command may be sent to the target MCU to request a timed sync response signal from which the host can determine the correct communication speed.

### Background debug controller (BDC)

BKGD is a pseudo-open-drain pin and there is an on-chip pullup so no external pullup resistor is required. Unlike typical open-drain pins, the external RC time constant on this pin, which is influenced by external capacitance, plays almost no role in signal rise time. The custom protocol provides for brief, actively driven speedup pulses to force rapid rise times on this pin without risking harmful drive level conflicts. Refer to Communication details for more detail.

When no debugger pod is connected to the 6-pin BDM interface connector, the internal pullup on BKGD chooses normal operating mode. When a debug pod is connected to BKGD it is possible to force the MCU into active background mode after reset. The specific conditions for forcing active background depend upon the HCS08 derivative (refer to the introduction to this Development Support section). It is not necessary to reset the target MCU to communicate with it through the background debug interface.

## 24.2.2 Communication details

The BDC serial interface requires the external controller to generate a falling edge on the BKGD pin to indicate the start of each bit time. The external controller provides this falling edge whether data is transmitted or received.

BKGD is a pseudo-open-drain pin that can be driven either by an external controller or by the MCU. Data is transferred MSB first at 16 BDC clock cycles per bit (nominal speed). The interface times out if 512 BDC clock cycles occur between falling edges from the host. Any BDC command that was in progress when this timeout occurs is aborted without affecting the memory or operating mode of the target MCU system.

The custom serial protocol requires the debug pod to know the target BDC communication clock speed.

The clock switch (CLKSW) control bit in the BDC status and control register allows the user to select the BDC clock source. The BDC clock source can either be the MSTRCLK or the alternate BDC clock source.

The BKGD pin can receive a high or low level or transmit a high or low level. The following diagrams show timing for each of these cases. Interface timing is synchronous to clocks in the target BDC, but asynchronous to the external host. The internal BDC clock signal is shown for reference in counting cycles.

The following figure shows an external host transmitting a logic 1 or 0 to the BKGD pin of a target HCS08 MCU. The host is asynchronous to the target so there is a 0-to-1 cycle delay from the host-generated falling edge to where the target perceives the beginning of the bit time. Ten target BDC clock cycles later, the target senses the bit level on the BKGD pin. Typically, the host actively drives the pseudo-open-drain BKGD pin during

**Chapter 24 Development support** 

host-to-target transmissions to speed up rising edges. Because the target does not drive the BKGD pin during the host-to-target transmission period, there is no need to treat the line as an open-drain signal during this period.

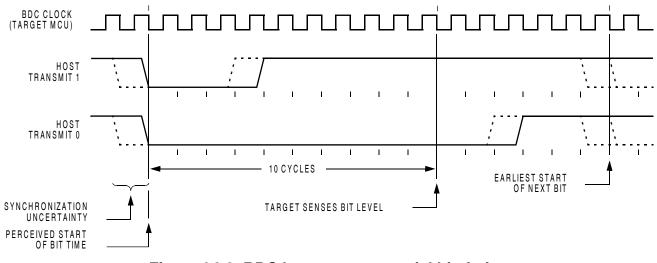

Figure 24-2. BDC host-to-target serial bit timing

The next figure shows the host receiving a logic 1 from the target HCS08 MCU. Because the host is asynchronous to the target MCU, there is a 0-to-1 cycle delay from the hostgenerated falling edge on BKGD to the perceived start of the bit time in the target MCU. The host holds the BKGD pin low long enough for the target to recognize it (at least two target BDC cycles). The host must release the low drive before the target MCU drives a brief active-high speedup pulse seven cycles after the perceived start of the bit time. The host should sample the bit level about 10 cycles after it started the bit time.

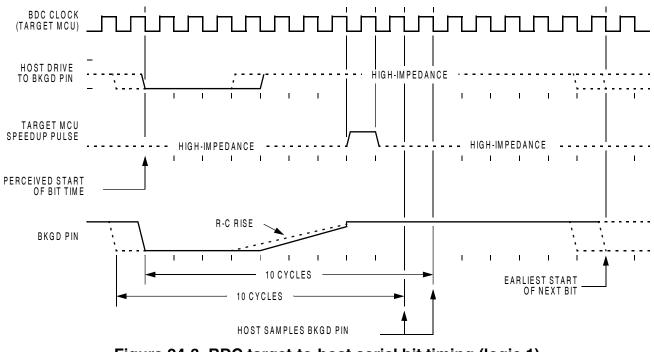

Figure 24-3. BDC target-to-host serial bit timing (logic 1)

MC9S08PL16S Reference Manual, Rev. 3, 06/2020

### Background debug controller (BDC)

The following figure shows the host receiving a logic 0 from the target HCS08 MCU. Because the host is asynchronous to the target MCU, there is a 0-to-1 cycle delay from the host-generated falling edge on BKGD to the start of the bit time as perceived by the target MCU. The host initiates the bit time but the target HCS08 finishes it. Because the target wants the host to receive a logic 0, it drives the BKGD pin low for 13 BDC clock cycles, then briefly drives it high to speed up the rising edge. The host samples the bit level about 10 cycles after starting the bit time.

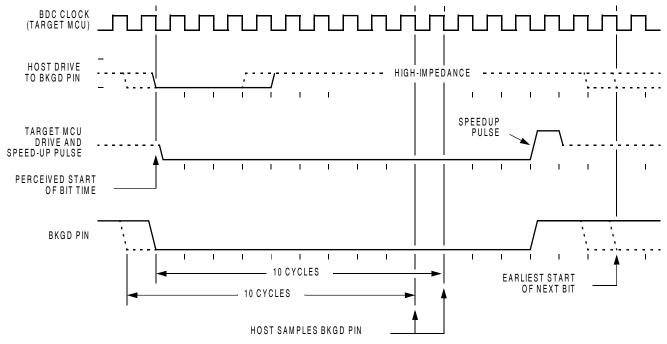

Figure 24-4. BDM target-to-host serial bit timing (logic 0)

## 24.2.3 BDC commands

BDC commands are sent serially from a host computer to the BKGD pin of the target HCS08 MCU. All commands and data are sent MSB-first using a custom BDC communications protocol. Active background mode commands require that the target MCU is currently in the active background mode while non-intrusive commands may be issued at any time whether the target MCU is in active background mode or running a user application program.

The following table shows all HCS08 BDC commands, a shorthand description of their coding structure, and the meaning of each command.

### **Coding Structure Nomenclature**

This nomenclature is used in the following table to describe the coding structure of the BDC commands.

Commands begin with an 8-bit hexadecimal command code in the host-to-target direction (most significant bit first) / =separates parts of the command d=delay 16 target BDC clock cycles AAAA = a 16-bit address in the host-to-target direction = 8 bits of read data in the target-to-host direction RD = 8 bits of write data in the host-to-target direction WD RD16 = 16 bits of read data in the target-to-host direction WD16 = 16 bits of write data in the host-to-target direction = the contents of BDCSCR in the target-to-host direction (STATUS) SS = 8 bits of write data for BDCSCR in the host-to-target direction (CONTROL) CC RBKP = 16 bits of read data in the target-to-host direction (from BDCBKPT breakpoint register) WBKP = 16 bits of write data in the host-to-target direction (for BDCBKPT breakpoint register)

Command mnemonic	Active BDM/ non-intrusive	Coding structure	Description
SYNC	Non-intrusive	N/A <sup>1</sup>	Request a timed reference pulse to determine target BDC communication speed
ACK_ENABLE	Non-intrusive	D5/d	Enable acknowledge protocol. Refer to NXP document order no. HCS08RMv1/D.
ACK_DISABLE	Non-intrusive	D6/d	Disable acknowledge protocol. Refer to NXP document order no. HCS08RMv1/D.
BACKGROUND	Non-intrusive	90/d	Enter active background mode if enabled (ignore if ENBDM bit equals 0)
READ_STATUS	Non-intrusive	E4/SS	Read BDC status from BDCSCR
WRITE_CONTROL	Non-intrusive	C4/CC	Write BDC controls in BDCSCR
READ_BYTE	Non-intrusive	E0/AAAA/d/RD	Read a byte from target memory
READ_BYTE_WS	Non-intrusive	E1/AAAA/d/SS/RD	Read a byte and report status
READ_LAST	Non-intrusive	E8/SS/RD	Re-read byte from address just read and report status
WRITE_BYTE	Non-intrusive	C0/AAAA/WD/d	Write a byte to target memory
WRITE_BYTE_WS	Non-intrusive	C1/AAAA/WD/d/SS	Write a byte and report status
READ_BKPT	Non-intrusive	E2/RBKP	Read BDCBKPT breakpoint register
WRITE_BKPT	Non-intrusive	C2/WBKP	Write BDCBKPT breakpoint register
GO	Active BDM	08/d	Go to execute the user application program starting at the address currently in the PC
TRACE1	Active BDM	10/d	Trace 1 user instruction at the address in the PC, then return to active background mode

### Table 24-1. BDC command summary

Table continues on the next page...

Command mnemonic	Active BDM/ non-intrusive	Coding structure	Description
TAGGO	Active BDM	18/d	Same as GO but enable external tagging (HCS08 devices have no external tagging pin)
READ_A	Active BDM	68/d/RD	Read accumulator (A)
READ_CCR	Active BDM	69/d/RD	Read condition code register (CCR)
READ_PC	Active BDM	6B/d/RD16	Read program counter (PC)
READ_HX	Active BDM	6C/d/RD16	Read H and X register pair (H:X)
READ_SP	Active BDM	6F/d/RD16	Read stack pointer (SP)
READ_NEXT	Active BDM	70/d/RD	Increment H:X by one then read memory byte located at H:X
READ_NEXT_WS	Active BDM	71/d/SS/RD	Increment H:X by one then read memory byte located at H:X. Report status and data.
WRITE_A	Active BDM	48/WD/d	Write accumulator (A)
WRITE_CCR	Active BDM	49/WD/d	Write condition code register (CCR)
WRITE_PC	Active BDM	4B/WD16/d	Write program counter (PC)
WRITE_HX	Active BDM	4C/WD16/d	Write H and X register pair (H:X)
WRITE_SP	Active BDM	4F/WD16/d	Write stack pointer (SP)
WRITE_NEXT	Active BDM	50/WD/d	Increment H:X by one, then write memory byte located at H:X
WRITE_NEXT_WS	Active BDM	51/WD/d/SS	Increment H:X by one, then write memory byte located at H:X. Also report status.

Table 24-1.	BDC command s	summarv (	(continued)	)
			0011111000	ι.

1. The SYNC command is a special operation that does not have a command code.

The SYNC command is unlike other BDC commands because the host does not necessarily know the correct communications speed to use for BDC communications until after it has analyzed the response to the SYNC command.

To issue a SYNC command, the host:

- Drives the BKGD pin low for at least 128 cycles of the slowest possible BDC clock (The slowest clock is normally the reference oscillator/64 or the self-clocked rate/ 64.)
- Drives BKGD high for a brief speedup pulse to get a fast rise time (This speedup pulse is typically one cycle of the fastest clock in the system.)
- Removes all drive to the BKGD pin so it reverts to high impedance
- Monitors the BKGD pin for the sync response pulse

The target, upon detecting the SYNC request from the host (which is a much longer low time than would ever occur during normal BDC communications):

- Waits for BKGD to return to a logic high
- Delays 16 cycles to allow the host to stop driving the high speedup pulse
- Drives BKGD low for 128 BDC clock cycles
- Drives a 1-cycle high speedup pulse to force a fast rise time on BKGD
- Removes all drive to the BKGD pin so it reverts to high impedance

The host measures the low time of this 128-cycle sync response pulse and determines the correct speed for subsequent BDC communications. Typically, the host can determine the correct communication speed within a few percent of the actual target speed and the communication protocol can easily tolerate speed errors of several percent.

## 24.2.4 BDC hardware breakpoint

The BDC includes one relatively simple hardware breakpoint that compares the CPU address bus to a 16-bit match value in the BDCBKPT register. This breakpoint can generate a forced breakpoint or a tagged breakpoint. A forced breakpoint causes the CPU to enter active background mode at the first instruction boundary following any access to the breakpoint address. The tagged breakpoint causes the instruction opcode at the breakpoint address to be tagged so that the CPU will enter active background mode rather than executing that instruction if and when it reaches the end of the instruction queue. This implies that tagged breakpoints can be placed only at the address of an instruction opcode while forced breakpoints can be set at any address.

The breakpoint enable (BKPTEN) control bit in the BDC status and control register (BDCSCR) is used to enable the breakpoint logic (BKPTEN = 1). When BKPTEN = 0, its default value after reset, the breakpoint logic is disabled and no BDC breakpoints are requested regardless of the values in other BDC breakpoint registers and control bits. The force/tag select (FTS) control bit in BDCSCR is used to select forced (FTS = 1) or tagged (FTS = 0) type breakpoints.

The on-chip debug module (DBG) includes circuitry for two additional hardware breakpoints that are more flexible than the simple breakpoint in the BDC module.

# 24.3 On-chip debug system (DBG)

Because HCS08 devices do not have external address and data buses, the most important functions of an in-circuit emulator have been built onto the chip with the MCU. The debug system consists of an 8-stage FIFO that can store address or data bus information,

### On-chip debug system (DBG)

and a flexible trigger system to decide when to capture bus information and what information to capture. The system relies on the single-wire background debug system to access debug control registers and to read results out of the eight stage FIFO.

The debug module includes control and status registers that are accessible in the user's memory map. These registers are located in the high register space to avoid using valuable direct page memory space.

Most of the debug module's functions are used during development, and user programs rarely access any of the control and status registers for the debug module. The one exception is that the debug system can provide the means to implement a form of ROM patching. This topic is discussed in greater detail in Hardware breakpoints.

## 24.3.1 Comparators A and B

Two 16-bit comparators (A and B) can optionally be qualified with the R/W signal and an opcode tracking circuit. Separate control bits allow you to ignore R/W for each comparator. The opcode tracking circuitry optionally allows you to specify that a trigger will occur only if the opcode at the specified address is actually executed as opposed to only being read from memory into the instruction queue. The comparators are also capable of magnitude comparisons to support the inside range and outside range trigger modes. Comparators are disabled temporarily during all BDC accesses.

The A comparator is always associated with the 16-bit CPU address. The B comparator compares to the CPU address or the 8-bit CPU data bus, depending on the trigger mode selected. Because the CPU data bus is separated into a read data bus and a write data bus, the RWAEN and RWA control bits have an additional purpose, in full address plus data comparisons they are used to decide which of these buses to use in the comparator B data bus comparisons. If RWAEN = 1 (enabled) and RWA = 0 (write), the CPU's write data bus is used. Otherwise, the CPU's read data bus is used.

The currently selected trigger mode determines what the debugger logic does when a comparator detects a qualified match condition. A match can cause:

- Generation of a breakpoint to the CPU
- Storage of data bus values into the FIFO
- Starting to store change-of-flow addresses into the FIFO (begin type trace)
- Stopping the storage of change-of-flow addresses into the FIFO (end type trace)

## 24.3.2 Bus capture information and FIFO operation

The usual way to use the FIFO is to setup the trigger mode and other control options, then arm the debugger. When the FIFO has filled or the debugger has stopped storing data into the FIFO, you would read the information out of it in the order it was stored into the FIFO. Status bits indicate the number of words of valid information that are in the FIFO as data is stored into it. If a trace run is manually halted by writing 0 to ARM before the FIFO is full (CNT = 1:0:0:0), the information is shifted by one position and the host must perform ((8 - CNT) - 1) dummy reads of the FIFO to advance it to the first significant entry in the FIFO.

In most trigger modes, the information stored in the FIFO consists of 16-bit change-offlow addresses. In these cases, read DBGFH then DBGFL to get one coherent word of information out of the FIFO. Reading DBGFL (the low-order byte of the FIFO data port) causes the FIFO to shift so the next word of information is available at the FIFO data port. In the event-only trigger modes (see Trigger modes), 8-bit data information is stored into the FIFO. In these cases, the high-order half of the FIFO (DBGFH) is not used and data is read out of the FIFO by simply reading DBGFL. Each time DBGFL is read, the FIFO is shifted so the next data value is available through the FIFO data port at DBGFL.

In trigger modes where the FIFO is storing change-of-flow addresses, there is a delay between CPU addresses and the input side of the FIFO. Because of this delay, if the trigger event itself is a change-of-flow address or a change-of-flow address appears during the next two bus cycles after a trigger event starts the FIFO, it will not be saved into the FIFO. In the case of an end-trace, if the trigger event is a change-of-flow, it will be saved as the last change-of-flow entry for that debug run.

The FIFO can also be used to generate a profile of executed instruction addresses when the debugger is not armed. When ARM = 0, reading DBGFL causes the address of the most-recently fetched opcode to be saved in the FIFO. To use the profiling feature, a host debugger would read addresses out of the FIFO by reading DBGFH then DBGFL at regular periodic intervals. The first eight values would be discarded because they correspond to the eight DBGFL reads needed to initially fill the FIFO. Additional periodic reads of DBGFH and DBGFL return delayed information about executed instructions so the host debugger can develop a profile of executed instruction addresses. On-chip debug system (DBG)

## 24.3.3 Change-of-flow information

To minimize the amount of information stored in the FIFO, only information related to instructions that cause a change to the normal sequential execution of instructions is stored. With knowledge of the source and object code program stored in the target system, an external debugger system can reconstruct the path of execution through many instructions from the change-of-flow information stored in the FIFO.

For conditional branch instructions where the branch is taken (branch condition was true), the source address is stored (the address of the conditional branch opcode). Because BRA and BRN instructions are not conditional, these events do not cause change-of-flow information to be stored in the FIFO.

Indirect JMP and JSR instructions use the current contents of the H:X index register pair to determine the destination address, so the debug system stores the run-time destination address for any indirect JMP or JSR. For interrupts, RTI, or RTS, the destination address is stored in the FIFO as change-of-flow information.

## 24.3.4 Tag vs. force breakpoints and triggers

Tagging is a term that refers to identifying an instruction opcode as it is fetched into the instruction queue, but not taking any other action until and unless that instruction is actually executed by the CPU. This distinction is important because any change-of-flow from a jump, branch, subroutine call, or interrupt causes some instructions that have been fetched into the instruction queue to be thrown away without being executed.

A force-type breakpoint waits for the current instruction to finish and then acts upon the breakpoint request. The usual action in response to a breakpoint is to go to active background mode rather than continuing to the next instruction in the user application program.

The tag vs. force terminology is used in two contexts within the debug module. The first context refers to breakpoint requests from the debug module to the CPU. The second refers to match signals from the comparators to the debugger control logic. When a tag-type break request is sent to the CPU, a signal is entered into the instruction queue along with the opcode so that if/when this opcode ever executes, the CPU will effectively replace the tagged opcode with a BGND opcode so the CPU goes to active background mode rather than executing the tagged instruction. When the TRGSEL control bit in the DBGT register is set to select tag-type operation, the output from comparator A or B is qualified by a block of logic in the debug module that tracks opcodes and produces only a trigger to the debugger if the opcode at the compare address is actually executed. There is separate opcode tracking logic for each comparator so more than one compare event can be tracked through the instruction queue at a time.

### MC9S08PL16S Reference Manual, Rev. 3, 06/2020

# 24.3.5 Trigger modes

The trigger mode controls the overall behavior of a debug run. The 4-bit TRG field in the DBGT register selects one of nine trigger modes. When TRGSEL = 1 in the DBGT register, the output of the comparator must propagate through an opcode tracking circuit before triggering FIFO actions. The BEGIN bit in DBGT chooses whether the FIFO begins storing data when the qualified trigger is detected (begin trace), or the FIFO stores data in a circular fashion from the time it is armed until the qualified trigger is detected (end trigger).

A debug run is started by writing a 1 to the ARM bit in the DBGC register, which sets the ARMF flag and clears the AF and BF flags and the CNT bits in DBGS. A begin-trace debug run ends when the FIFO gets full. An end-trace run ends when the selected trigger event occurs. Any debug run can be stopped manually by writing a 0 to ARM or DBGEN in DBGC.

In all trigger modes except event-only modes, the FIFO stores change-of-flow addresses. In event-only trigger modes, the FIFO stores data in the low-order eight bits of the FIFO.

The BEGIN control bit is ignored in event-only trigger modes and all such debug runs are begin type traces. When TRGSEL = 1 to select opcode fetch triggers, it is not necessary to use R/W in comparisons because opcode tags would apply only to opcode fetches that are always read cycles. It would also be unusual to specify TRGSEL = 1 while using a full mode trigger because the opcode value is normally known at a particular address.

The following trigger mode descriptions state only the primary comparator conditions that lead to a trigger. Either comparator can usually be further qualified with R/W by setting RWAEN (RWBEN) and the corresponding RWA (RWB) value to be matched against R/W. The signal from the comparator with optional R/W qualification is used to request a CPU breakpoint if BRKEN = 1 and TAG determines whether the CPU request will be a tag request or a force request.

A-Only- Trigger when the address matches the value in comparator A

**A OR B-** Trigger when the address matches either the value in comparator A or the value in comparator B

**A Then B-** Trigger when the address matches the value in comparator B but only after the address for another cycle matched the value in comparator A. There can be any number of cycles after the A match and before the B match.

#### On-chip debug system (DBG)

A AND B Data (Full Mode)- This is called a full mode because address, data, and R/W (optionally) must match within the same bus cycle to cause a trigger event. Comparator A checks address, the low byte of comparator B checks data, and R/W is checked against RWA if RWAEN = 1. The high-order half of comparator B is not used.

In full trigger modes it is not useful to specify a tag-type CPU breakpoint (BRKEN = TAG = 1), but if you do, the comparator B data match is ignored for the purpose of issuing the tag request to the CPU and the CPU breakpoint is issued when the comparator A address matches.

A AND NOT B Data (Full Mode)- Address must match comparator A, data must not match the low half of comparator B, and R/W must match RWA if RWAEN = 1. All three conditions must be met within the same bus cycle to cause a trigger.

In full trigger modes it is not useful to specify a tag-type CPU breakpoint (BRKEN = TAG = 1), but if you do, the comparator B data match is ignored for the purpose of issuing the tag request to the CPU and the CPU breakpoint is issued when the comparator A address matches.

**Event-Only B (Store Data)** Trigger events occur each time the address matches the value in comparator B. Trigger events cause the data to be captured into the FIFO. The debug run ends when the FIFO becomes full.

A Then Event-Only B (Store Data)- After the address has matched the value in comparator A, a trigger event occurs each time the address matches the value in comparator B. Trigger events cause the data to be captured into the FIFO. The debug run ends when the FIFO becomes full.

**Inside Range (A \leq Address \leq B)**- A trigger occurs when the address is greater than or equal to the value in comparator A and less than or equal to the value in comparator B at the same time.

**Outside Range (Address < A or Address > B)-** A trigger occurs when the address is either less than the value in comparator A or greater than the value in comparator B.

# 24.3.6 Hardware breakpoints

The BRKEN control bit in the DBGC register may be set to 1 to allow any of the trigger conditions described in Trigger modes to be used to generate a hardware breakpoint request to the CPU. TAG in DBGC controls whether the breakpoint request will be treated as a tag-type breakpoint or a force-type breakpoint. A tag breakpoint causes the current opcode to be marked as it enters the instruction queue. If a tagged opcode reaches

the end of the pipe, the CPU executes a BGND instruction to go to active background mode rather than executing the tagged opcode. A force-type breakpoint causes the CPU to finish the current instruction and then go to active background mode.

If the background mode has not been enabled (ENBDM = 1) by a serial WRITE\_CONTROL command through the BKGD pin, the CPU will execute an SWI instruction instead of going to active background mode.

# 24.4 Memory map and register description

This section contains the descriptions of the BDCand DBG registers and control bits. Refer to the high-page register summary in the device overview chapter of this data sheet for the absolute address assignments for all DBG registers. This section refers to registers and control bits only by their names. An NXP-provided equate or header file is used to translate these names into the appropriate absolute addresses.

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	BDC Status and Control Register (BDC_SCR)	8	R/W	00h	24.4.1/399
1	BDC Breakpoint Match Register: High (BDC_BKPTH)	8	R/W	00h	24.4.2/401
2	BDC Breakpoint Register: Low (BDC_BKPTL)	8	R/W	00h	24.4.3/402
3	System Background Debug Force Reset Register (BDC_SBDFR)	8	W (always reads 0)	00h	24.4.4/402

#### **BDC** memory map

# 24.4.1 BDC Status and Control Register (BDC\_SCR)

This register can be read or written by serial BDC commands (READ\_STATUS and WRITE\_CONTROL) but is not accessible to user programs because it is not located in the normal memory map of the MCU.

### NOTE

The reset values shown in the register figure are those in the normal reset conditions. If the MCU is reset in BDM, ENBDM, BDMACT, CLKSW will be reset to 1 and others all be to 0.

BDC Breakpoint Enable
Kakis bit is shown the DDO has shown in the discribution of the FTO (1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1
If this bit is clear, the BDC breakpoint is disabled and the FTS (force tag select) control bit and BDCBKPT match register are ignored.
0 BDC breakpoint disabled.
1 BDC breakpoint enabled.
Force/Tag Select
When $FTS = 1$ , a breakpoint is requested whenever the CPU address bus matches the BDCBKPT match register. When $FTS = 0$ , a match between the CPU address bus and the BDCBKPT register causes the fetched opcode to be tagged. If this tagged opcode ever reaches the end of the instruction queue, the CPU enters active background mode rather than executing the tagged opcode.
0 Tag opcode at breakpoint address and enter active background mode if CPU attempts to execute that instruction
1 Breakpoint match forces active background mode at next instruction boundary (address need not be an opcode)
Select Source for BDC Communications Clock
CLKSW defaults to 0, which selects the alternate BDC clock source.
0 Alternate BDC clock source.
1 MCU MSTRCLK.
Wait or Stop Status
When the target CPU is in wait or stop mode, most BDC commands cannot function. However, the BACKGROUND command can be used to force the target CPU out of wait or stop and into active background mode where all BDC commands work. Whenever the host forces the target MCU into active background mode, the host should issue a READ_STATUS command to check that BDMACT = 1 before attempting other BDC commands.

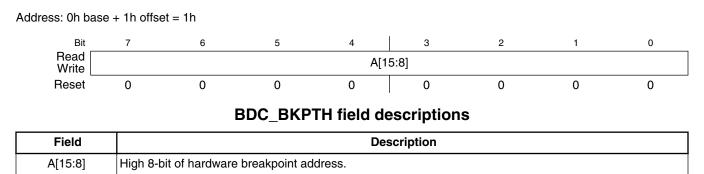

Table continues on the next page ...

Field	Description								
	0 Target CPU is running user application code or in active background mode (was not in wait or stop mode when background became active).								
	1 Target CPU is in wait or stop mode, or a BACKGROUND command was used to change from wait or stop to active background mode.								
1	Wait or Stop Failure Status								
WSF									
	This status bit is set if a memory access command failed due to the target CPU executing a wait or stop instruction at or about the same time. The usual recovery strategy is to issue a BACKGROUND comman to get out of wait or stop mode into active background mode, repeat the command that failed, then return to the user program. (Typically, the host would restore CPU registers and stack values and re-execute th wait or stop instruction.)								
	0 Memory access did not conflict with a wait or stop instruction.								
	1 Memory access command failed because the CPU entered wait or stop mode.								
0 DVF	Data Valid Failure Status								
	0 Memory access did not conflict with a slow memory access								
	1 Memory access command failed because CPU was not finished with a slow memory access.								

#### **BDC\_SCR field descriptions (continued)**

## 24.4.2 BDC Breakpoint Match Register: High (BDC\_BKPTH)

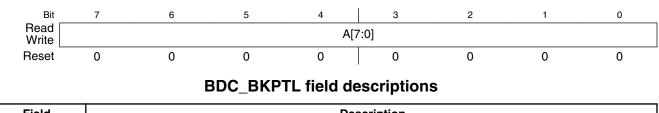

This register, together with BDC\_BKPTL, holds the address for the hardware breakpoint in the BDC. The BKPTEN and FTS control bits in BDCSCR are used to enable and configure the breakpoint logic. Dedicated serial BDC commands (READ\_BKPT and WRITE\_BKPT) are used to read and write the BDCBKPT register but is not accessible to user programs because it is not located in the normal memory map of the MCU. Breakpoints are normally set while the target MCU is in active background mode before running the user application program.

# 24.4.3 BDC Breakpoint Register: Low (BDC\_BKPTL)

BDC\_BKPTH and BDC\_BKPTL registers hold the address for the hardware breakpoint in the BDC. The BDC\_SCR[FTS] and BDC\_SCR[BKPTEN] bits are used to enable and configure the breakpoint logic. Dedicated serial BDC commands (READ\_BKPT and WRITE\_BKPT) are used to read and write the BDC\_BKPTH and BDC\_BKPTL register. Breakpoints are normally set while the target MCU is in background debug mode before running the user application program. However, since READ\_BKPT and WRITE\_BKPT are foreground commands, they could be executed even while the user program is running.

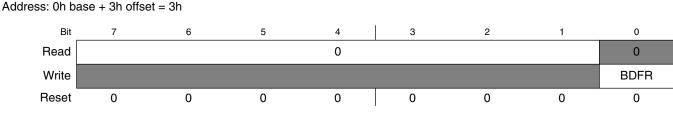

Address: 0h base + 2h offset = 2h

Field	Description
A[7:0]	Low 8-bit of hardware breakpoint address.

# 24.4.4 System Background Debug Force Reset Register (BDC\_SBDFR)

This register contains a single write-only control bit. A serial background mode command such as WRITE\_BYTE must be used to write to SBDFR. Attempts to write this register from a user program are ignored. Reads always return 0x00.

#### BDC\_SBDFR field descriptions

Field	Description
7–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 BDFR	Background Debug Force Reset

Table continues on the next page ...

#### MC9S08PL16S Reference Manual, Rev. 3, 06/2020

### BDC\_SBDFR field descriptions (continued)

Field	Description
	A serial active background mode command such as WRITE_BYTE allows an external debug host to force a target system reset. Writing 1 to this bit forces an MCU reset. This bit cannot be written from a user program.

#### Memory map and register description

# Chapter 25 Debug module (DBG)

# 25.1 Introduction

The DBG module implements an on-chip ICE (in-circuit emulation) system and allows non-intrusive debug of application software by providing an on-chip trace buffer with flexible triggering capability. The trigger also can provide extended breakpoint capacity. The on-chip ICE system is optimized for the S08CPUV6 8-bit architecture and supports 2 M bytes of memory space.

# 25.1.1 Features

The on-chip ICE system includes these distinctive features:

- Three comparators (A, B, and C) with ability to match addresses in 64 KB space
  - Dual mode, Comparators A and B used to compare addresses
  - Full mode, Comparator A compares address and Comparator B compares data
  - Can be used as triggers and/or breakpoints
  - Comparator C can be used as a normal hardware breakpoint
  - Loop1 capture mode, Comparator C is used to track most recent COF event captured into FIFO
- Tag and Force type breakpoints
- Nine trigger modes
  - A
  - A Or B
  - A then B
  - A and B, where B is data (full mode)
  - A and not B, where B is data (full mode)
  - Event only B, store data
  - A then event only B, store data
  - Inside range,  $A \le address \le B$
  - Outside range, address < A or address > B

#### Introduction

- FIFO for storing change of flow information and event only data
  - Source address of conditional branches taken
  - Destination address of indirect JMP and JSR instruction
  - Destination address of interrupts, RTI, RTC, and RTS instruction
  - Data associated with Event B trigger modes
- Ability to End-trace until reset and begin-trace from reset

# 25.1.2 Modes of operation

The on-chip ICE system can be enabled in all MCU functional modes. The DBG module is disabled if the MCU is secure. The DBG module comparators are disabled when executing a Background Debug Mode (BDM) command.

## 25.1.3 Block diagram

The following figure shows the structure of the DBG module.

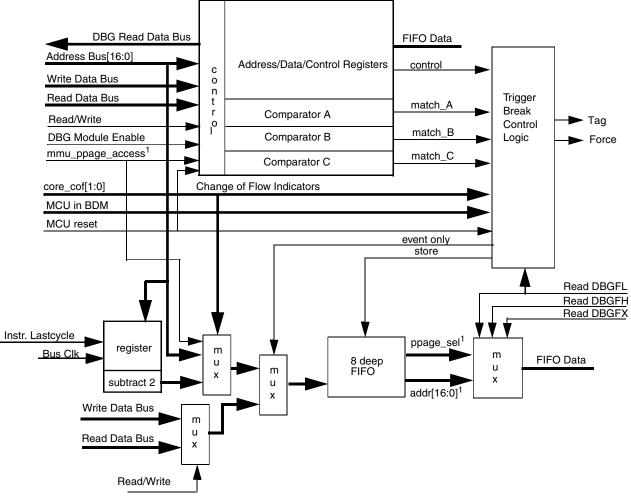

Figure 25-1. DBG block diagram

# 25.2 Signal description

The DBG module contains no external signals.

# 25.3 Memory map and registers

This section provides a detailed description of all DBG registers accessible to the end user.

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
3010	Debug Comparator A High Register (DBG_CAH)	8	R/W	FFh	25.3.1/408
3011	Debug Comparator A Low Register (DBG_CAL)	8	R/W	FEh	25.3.2/409
3012	Debug Comparator B High Register (DBG_CBH)	8	R/W	00h	25.3.3/410
3013	Debug Comparator B Low Register (DBG_CBL)	8	R/W	00h	25.3.4/410
3014	Debug Comparator C High Register (DBG_CCH)	8	R/W	00h	25.3.5/411
3015	Debug Comparator C Low Register (DBG_CCL)	CL) 8 R/W 00h			25.3.6/412
3016	Debug FIFO High Register (DBG_FH)	8	R	00h	25.3.7/412
3017	Debug FIFO Low Register (DBG_FL)	8	R	00h	25.3.8/413
3018	Debug Comparator A Extension Register (DBG_CAX)	8	R/W	00h	25.3.9/414
3019	Debug Comparator B Extension Register (DBG_CBX)	8	R/W	00h	25.3.10/415
301A	Debug Comparator C Extension Register (DBG_CCX)	8	R/W	00h	25.3.11/416
301B	Debug FIFO Extended Information Register (DBG_FX)	8	R	00h	25.3.12/417

#### **DBG memory map**

# 25.3.1 Debug Comparator A High Register (DBG\_CAH)

#### NOTE

All the bits in this register reset to 1 in POR or non-end-run reset. The bits are undefined in end-run reset. In the case of an end-trace to reset where DBGEN = 1 and BEGIN = 0, the bits in this register do not change after reset.

Address: 3010h base + 0h offset = 3010h

Bit	7	6	5	4	3	2	1	0	
Read Write		CA[15:8]							
Reset	1	1	1	1	1	1	1	1	

#### **DBG\_CAH** field descriptions

Field	Description
CA[15:8]	Comparator A High Compare Bits
	The Comparator A High compare bits control whether Comparator A will compare the address bus bits [15:8] to a logic 1 or logic 0.

Chapter 25 Debug module (DBG)

#### DBG\_CAH field descriptions (continued)

Field	Description						
	0 Compare corresponding address bit to a logic 0.						
	1 Compare corresponding address bit to a logic 1.						

## 25.3.2 Debug Comparator A Low Register (DBG\_CAL)

#### NOTE

All the bits in this register reset to 1 in POR or non-end-run reset. The bits are undefined in end-run reset. In the case of an end-trace to reset where DBGEN = 1 and BEGIN = 0, the bits in this register do not change after reset.

Address: 3010h base + 1h offset = 3011h

Bit	7	6	5	4	3	2	1	0
Read Write	CA[7:0]							
Reset	1	1	1	1	1	1	1	0

#### **DBG\_CAL** field descriptions

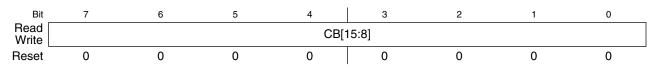

Field	Description
CA[7:0]	Comparator A Low
	The Comparator A Low compare bits control whether Comparator A will compare the address bus bits [7:0] to a logic 1 or logic 0.
	0 Compare corresponding address bit to a logic 0.
	1 Compare corresponding address bit to a logic 1.

# 25.3.3 Debug Comparator B High Register (DBG\_CBH)

#### NOTE

All the bits in this register reset to 0 in POR or non-end-run reset. The bits are undefined in end-run reset. In the case of an end-trace to reset where DBGEN = 1 and BEGIN = 0, the bits in this register do not change after reset.

Address: 3010h base + 2h offset = 3012h

#### DBG\_CBH field descriptions

Field	Description			
CB[15:8]	Comparator B High Compare Bits			
	The Comparator B High compare bits control whether Comparator B will compare the address bus bits [15:8] to a logic 1 or logic 0.Not used in full mode.			
	0 Compare corresponding address bit to a logic 0.			
	1 Compare corresponding address bit to a logic 1.			

### 25.3.4 Debug Comparator B Low Register (DBG\_CBL)

#### NOTE

All the bits in this register reset to 0 in POR or non-end-run reset. The bits are undefined in end-run reset. In the case of an end-trace to reset where DBGEN = 1 and BEGIN = 0, the bits in this register do not change after reset.

Address: 3010h base + 3h offset = 3013h

Bit	7	6	5	4	3	2	1	0
Read Write				CB[	7:0]			
Reset	0	0	0	0	0	0	0	0

#### DBG\_CBL field descriptions

Field	Description				
CB[7:0]	Comparator B Low				
	The Comparator B Low compare bits control whether Comparator B will compare the address bus bits [7:0] to a logic 1 or logic 0.				
	0 Compare corresponding address bit to a logic 0.				
	1 Compare corresponding address bit to a logic 1.				

### 25.3.5 Debug Comparator C High Register (DBG\_CCH)

#### NOTE

All the bits in this register reset to 0 in POR or non-end-run reset. The bits are undefined in end-run reset. In the case of an end-trace to reset where DBGEN = 1 and BEGIN = 0, the bits in this register do not change after reset.

Address: 3010h base + 4h offset = 3014h

Bit	7	6	5	4	3	2	1	0
Read Write				CC[	15:8]			
Reset	0	0	0	0	0	0	0	0

#### DBG\_CCH field descriptions

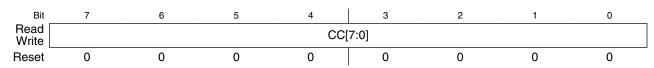

Field	Description				
CC[15:8]	Comparator C High Compare Bits				
	The Comparator C High compare bits control whether Comparator C will compare the address bus bits [15:8] to a logic 1 or logic 0.				
	0 Compare corresponding address bit to a logic 0.				
	1 Compare corresponding address bit to a logic 1.				

# 25.3.6 Debug Comparator C Low Register (DBG\_CCL)

#### NOTE

All the bits in this register reset to 0 in POR or non-end-run reset. The bits are undefined in end-run reset. In the case of an end-trace to reset where DBGEN = 1 and BEGIN = 0, the bits in this register do not change after reset.

Address: 3010h base + 5h offset = 3015h

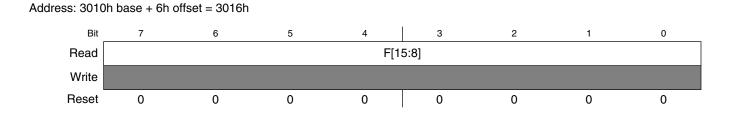

#### DBG\_CCL field descriptions

Field	Description				
CC[7:0]	Comparator C Low				
	The Comparator C Low compare bits control whether Comparator C will compare the address bus bits [7:0] to a logic 1 or logic 0.				
	0 Compare corresponding address bit to a logic 0.				
	1 Compare corresponding address bit to a logic 1.				

## 25.3.7 Debug FIFO High Register (DBG\_FH)

#### NOTE

All the bits in this register reset to 0 in POR or non-end-run reset. The bits are undefined in end-run reset. In the case of an end-trace to reset where DBGEN = 1 and BEGIN = 0, the bits in this register do not change after reset.

#### DBG\_FH field descriptions

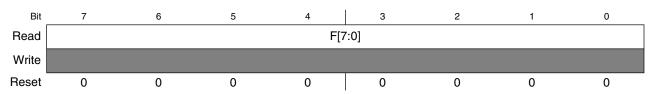

Field	Description
F[15:8]	FIFO High Data Bits
	The FIFO High data bits provide access to bits [15:8] of data in the FIFO. This register is not used in event only modes and will read a \$00 for valid FIFO words.

# 25.3.8 Debug FIFO Low Register (DBG\_FL)

#### NOTE

All the bits in this register reset to 0 in POR or non-end-run reset. The bits are undefined in end-run reset. In the case of an end-trace to reset where DBGEN = 1 and BEGIN = 0, the bits in this register do not change after reset.

Address: 3010h base + 7h offset = 3017h

#### DBG\_FL field descriptions

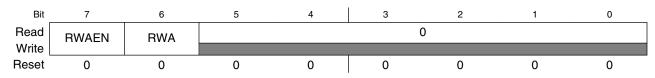

Field	Description
	FIFO Low Data Bits The FIFO Low data bits contain the least significant byte of data in the FIFO. When reading FIFO words, read DBGFX and DBGFH before reading DBGFL because reading DBGFL causes the FIFO pointers to advance to the next FIFO location. In event-only modes, there is no useful information in DBGFX and DBGFH so it is not necessary to read them before reading DBGFL.

# 25.3.9 Debug Comparator A Extension Register (DBG\_CAX)

#### NOTE

All the bits in this register reset to 0 in POR or non-end-run reset. The bits are undefined in end-run reset. In the case of an end-trace to reset where DBGEN = 1 and BEGIN = 0, the bits in this register do not change after reset.

Address: 3010h base + 8h offset = 3018h

#### DBG\_CAX field descriptions

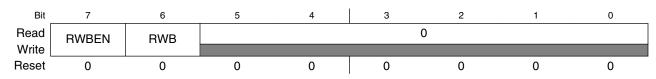

Field	Description		
7	Read/Write Comparator A Enable Bit		
RWAEN	The RWAEN bit controls whether read or write comparison is enabled for Comparator A.		
	0 Read/Write is not used in comparison.		
	1 Read/Write is used in comparison.		
6	Read/Write Comparator A Value Bit		
RWA	The RWA bit controls whether read or write is used in compare for Comparator A. The RWA bit is not used if RWAEN = 0.		
	0 Write cycle will be matched.		
	1 Read cycle will be matched.		
Reserved	This field is reserved.		
	This read-only field is reserved and always has the value 0.		

# 25.3.10 Debug Comparator B Extension Register (DBG\_CBX)

#### NOTE

All the bits in this register reset to 0 in POR or non-end-run reset. The bits are undefined in end-run reset. In the case of an end-trace to reset where DBGEN = 1 and BEGIN = 0, the bits in this register do not change after reset.

Address: 3010h base + 9h offset = 3019h

#### DBG\_CBX field descriptions

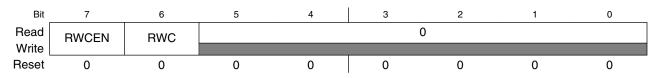

Field	Description
	Read/Write Comparator B Enable Bit
RWBEN	The RWBEN bit controls whether read or write comparison is enabled for Comparator B. In full modes, RWAEN and RWA are used to control comparison of R/W and RWBEN is ignored.
	0 Read/Write is not used in comparison.
	1 Read/Write is used in comparison.
6 RWB	Read/Write Comparator B Value Bit
	The RWB bit controls whether read or write is used in compare for Comparator B. The RWB bit is not used if RWBEN = 0.In full modes, RWAEN and RWA are used to control comparison of R/W and RWB is ignored.
	0 Write cycle will be matched.
	1 Read cycle will be matched.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

# 25.3.11 Debug Comparator C Extension Register (DBG\_CCX)

#### NOTE

All the bits in this register reset to 0 in POR or non-end-run reset. The bits are undefined in end-run reset. In the case of an end-trace to reset where DBGEN = 1 and BEGIN = 0, the bits in this register do not change after reset.

Address: 3010h base + Ah offset = 301Ah

#### DBG\_CCX field descriptions

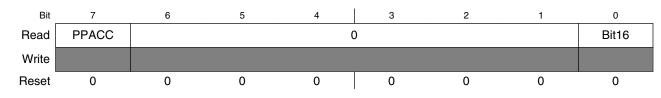

Field	Description
	Read/Write Comparator C Enable Bit
RWCEN	The RWCEN bit controls whether read or write comparison is enabled for Comparator C.
	0 Read/Write is not used in comparison.
	1 Read/Write is used in comparison.
6	Read/Write Comparator C Value Bit
RWC	The RWC bit controls whether read or write is used in compare for Comparator C. The RWC bit is not used if RWCEN = 0.
	0 Write cycle will be matched.
	1 Read cycle will be matched.
Reserved	This field is reserved.
	This read-only field is reserved and always has the value 0.

# 25.3.12 Debug FIFO Extended Information Register (DBG\_FX)

#### NOTE

All the bits in this register reset to 0 in POR or non-end-run reset. The bits are undefined in end-run reset. In the case of an end-trace to reset where DBGEN = 1 and BEGIN = 0, the bits in this register do not change after reset.

Address: 3010h base + Bh offset = 301Bh

#### **DBG\_FX** field descriptions

Field	Description				
7	PPAGE Access Indicator Bit				
PPACC					
	This bit indicates whether the captured information in the current FIFO word is associated with an extended access through the PPAGE mechanism or not. This is indicated by the internal signal mmu_ppage_sel which is 1 when the access is through the PPAGE mechanism.				
	0 The information in the corresponding FIFO word is event-only data or an unpaged 17-bit CPU address with bit-16 = 0.				
	1 The information in the corresponding FIFO word is a 17-bit flash address with PPAGE[2:0] in the three most significant bits and CPU address[13:0] in the 14 least significant bits.				
6–1	This field is reserved.				
Reserved	This read-only field is reserved and always has the value 0.				
0 Bit16	Extended Address Bit 16				
	This bit is the most significant bit of the 17-bit core address.				

## 25.3.13 Debug Control Register (DBG\_C)

Address: 3010h base + Ch offset = 301Ch

Bit	7	6	5	4	3	2	1	0
Read Write	DBGEN	ARM	TAG	BRKEN		0		LOOP1
Reset	1	1	0	0	0	0	0	0

MC9S08PL16S Reference Manual, Rev. 3, 06/2020

Field	Description			
7 DBGEN	DBG Module Enable Bit The DBGEN bit enables the DBG module. The DBGEN bit is forced to zero and cannot be set if the MCU is secure.			
	<ul><li>0 DBG not enabled.</li><li>1 DBG enabled.</li></ul>			
6 ARM	Arm Bit The ARM bit controls whether the debugger is comparing and storing data in FIFO.			
	<ol> <li>Debugger not armed.</li> <li>Debugger armed.</li> </ol>			
5 TAG	Tag or Force Bit The TAG bit controls whether a debugger or comparator C breakpoint will be requested as a tag or force breakpoint to the CPU. The TAG bit is not used if BRKEN = 0.			
	<ul><li>0 Force request selected.</li><li>1 Tag request selected.</li></ul>			
4 BRKEN	<ul> <li>Break Enable Bit</li> <li>The BRKEN bit controls whether the debugger will request a breakpoint to the CPU at the end of a trace run, and whether comparator C will request a breakpoint to the CPU.</li> <li>CPU break request not enabled.</li> <li>CPU break request enabled.</li> </ul>			
3–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.			
0 LOOP1	Select LOOP1 Capture Mode This bit selects either normal capture mode or LOOP1 capture mode. LOOP1 is not used in event-only modes.			
	<ul> <li>Normal operation - capture COF events into the capture buffer FIFO.</li> <li>LOOP1 capture mode enabled. When the conditions are met to store a COF value into the FIFO, compare the current COF address with the address in comparator C. If these addresses match, override the FIFO capture and do not increment the FIFO count. If the address does not match comparator C, capture the COF address, including the PPACC indicator, into the FIFO and into comparator C</li> </ul>			

#### DBG\_C field descriptions

# 25.3.14 Debug Trigger Register (DBG\_T)

### NOTE

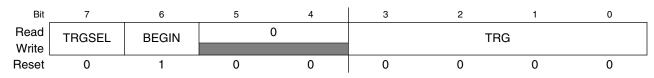

The figure shows the values in POR or non-end-run reset. All the bits are undefined in end-run reset. In the case of an endtrace to reset where DBGEN=1 and BEGIN=0, the ARM and BRKEN bits are cleared but the remaining control bits in this register do not change after reset.

#### MC9S08PL16S Reference Manual, Rev. 3, 06/2020

### NOTE

# The DBG trigger register (DBGT) can not be changed unless ARM=0.

Address: 3010h base + Dh offset = 301Dh

#### DBG\_T field descriptions

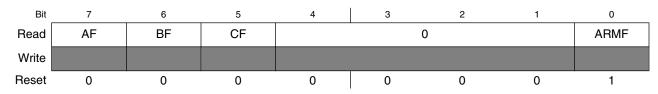

Field	Description			
7	Trigger Sele	ction Bit		
TRGSEL	The TRGSE	L bit controls the triggering condition for the comparators.		
	0 Trigger on any compare address access.			
	1 Trigger if opcode at compare address is execute.			
6	Begin/End Trigger Bit			
BEGIN		hit controls whether the trigger begins or and storing of data in EIEO		
		bit controls whether the trigger begins or ends storing of data in FIFO.		
	0 Trigger at end of stored data.			
	1 Trigger before storing data.			
5–4	This field is reserved.			
Reserved	This read-only field is reserved and always has the value 0.			
TRG	Trigger Mode Bits			
	The TRG bits select the trigger mode of the DBG module.			
	0000	A only.		
	0001	A or B.		
	0010	A then B.		
0011 Event only B. 0100 A then event only E		Event only B.		
		A then event only B.		
	A and B (full mode).			
	A and not B (full mode).			
	0111	Inside range.		
1000 Outside range.				
	1001-1111	No trigger.		

# 25.3.15 Debug Status Register (DBG\_S)

#### NOTE

The figure shows the values in POR or non-end-run reset. The bits of AF, BF and CF are undefined and ARMF is reset to 0 in end-run reset. In the case of an end-trace to reset where DBGEN=1 and BEGIN=0, ARMF gets cleared by reset but AF, BF, and CF do not change after reset.

Address: 3010h base + Eh offset = 301Eh

#### DBG\_S field descriptions

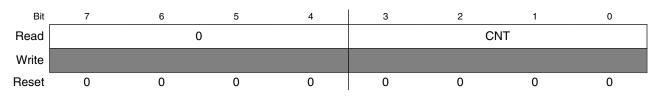

Field	Description				
7 AF	Trigger A Match Bit				
	The AF bit indicates if Trigger A match condition was met since arming.				
	0 Comparator A did not match.				
	1 Comparator A match.				
6 BF	Trigger B Match Bit				
	The BF bit indicates if Trigger B match condition was met since arming.				
	0 Comparator B did not match.				
	1 Comparator B match.				
5 CF	Trigger C Match Bit				
	The CF bit indicates if Trigger C match condition was met since arming.				
	0 Comparator C did not match.				
	1 Comparator C match.				
4–1	This field is reserved.				
Reserved	This read-only field is reserved and always has the value 0.				
0 ARMF	Arm Flag Bit				
	The ARMF bit indicates whether the debugger is waiting for trigger or waiting for the FIFO to fill. While DBGEN = 1, this status bit is a read-only image of the ARM bit in DBGC.				
	0 Debugger not armed.				
	1 Debugger armed.				

# 25.3.16 Debug Count Status Register (DBG\_CNT)

#### NOTE

All the bits in this register reset to 0 in POR or non-end-run reset. The bits are undefined in end-run reset. In the case of an end-trace to reset where DBGEN = 1 and BEGIN = 0, the CNT[3:0] bits do not change after reset.

Address: 3010h base + Fh offset = 301Fh

### DBG\_CNT field descriptions

Field	Description				
7–4	This field is reserved.				
Reserved	This read-only field is reserved and always has the value 0.				
CNT	FIFO Valid Count Bits The CNT bits indicate the amount of valid data stored in the FIFO. Table 1-20 shows the correlation between the CNT bits and the amount of valid data in FIFO. The CNT will stop after a count to eight even if more data is being stored in the FIFO. The CNT bits are cleared when the DBG module is armed, and the count is incremented each time a new word is captured into the FIFO. The host development system i responsible for checking the value in CNT[3:0] and reading the correct number of words from the FIFO because the count does not decrement as data is read out of the FIFO at the end of a trace run.				
	0000 No data valid.				
	0001 1 word valid.				
	0010 2 words valid.				
	0011 3 words valid.				
	0100 4 words valid.				
	0101 5 words valid.				
	0110 6 words valid.				
	0111 7 words valid.				
	1000 8 words valid.				

# 25.4 Functional description

This section provides a complete functional description of the on-chip ICE system. The DBG module is enabled by setting the DBG\_C[DBGEN] bit. Enabling the module allows the arming, triggering and storing of data in the FIFO. The DBG module is made up of three main blocks, the comparators, trigger break control logic and the FIFO.

# 25.4.1 Comparator

The DBG module contains three comparators, A, B, and C. Comparator A compares the core address bus with the address stored in the DBG\_CAH and DBG\_CAL registers. Comparator B compares the core address bus with the address stored in the DBG\_CBH and DBG\_CBL registers except in full mode, where it compares the data buses to the data stored in the DBG\_CBL register. Comparator C compares the core address bus with the address stored in the DBG\_CBL register. Address the core address bus with the address stored in the DBG\_CBL register. Comparator C compares the core address bus with the address stored in the DBG\_CCH and DBG\_CCL registers. Matches on comparators A, B, and C are signaled to the trigger break control (TBC) block.

# 25.4.1.1 RWA and RWAEN in full modes

In full modes ("A And B" and "A And Not B") DBG\_CAX[RWAEN and DBG\_CAX[RWA] are used to select read or write comparisons for both comparators A and B. To select write comparisons and the write data bus in Full Modes set DBG\_CAX[RWAEN] = 1 and DBG\_CAX[RWA] = 0, otherwise read comparisons and the read data bus will be selected. The DBG\_CBX[RWBEN] and DBG\_CBX[RWB] bits are not used and will be ignored in full modes.

# 25.4.1.2 Comparator C in loop1 capture mode

Normally comparator C is used as a third hardware breakpoint and is not involved in the trigger logic for the on-chip ICE system. In this mode, it compares the core address bus with the address stored in the DBG\_CCX, DBG\_CCH, and DBG\_CCL registers. However, in loop1 capture mode, comparator C is managed by logic in the DBG module to track the address of the most recent change-of-flow event that was captured into the FIFO buffer. In loop1 capture mode, comparator C is not available for use as a normal hardware breakpoint.

When the DBG\_C[ARM] and DBG\_C[DBGEN] bits are set to one in loop1 capture mode, comparator C value registers are cleared to prevent the previous contents of these registers from interfering with the loop1 capture mode operation. When a COF event is detected, the address of the event is compared to the contents of the DBG\_CCH and DBG\_CCL registers to determine whether it is the same as the previous COF entry in the capture FIFO. If the values match, the capture is inhibited to prevent the FIFO from filling up with duplicate entries. If the values do not match, the COF event is captured into the FIFO and the DBG\_CCH and DBG\_CCL registers are updated to reflect the address of the captured COF event.

# 25.4.2 Breakpoints

A breakpoint request to the CPU at the end of a trace run can be created if the DBG\_C[BRKEN] bit is set. The value of the DBG\_T[BEGIN] bit determines when the breakpoint request to the CPU will occur. If the DBG\_T[BEGIN] bit is set, begin-trigger is selected and the breakpoint request will not occur until the FIFO is filled with 8 words. If the DBG\_T[BEGIN] bit is cleared, end-trigger is selected and the breakpoint request will occur immediately at the trigger cycle.

When traditional hardware breakpoints from comparators A or B are desired, set  $DBG_T[BEGIN] = 0$  to select an end-trace run and set the trigger mode to either 0x0 (A-only) or 0x1 (A OR B) mode.

There are two types of breakpoint requests supported by the DBG module, tag-type and force-type. Tagged breakpoints are associated with opcode addresses and allow breaking just before a specific instruction executes. Force breakpoints are not associated with opcode addresses. The DBG\_C[TAG] bit determines whether CPU breakpoint requests will be a tag-type or force-type breakpoints. When DBG\_C[TAG] = 0, a force-type breakpoint is requested and it will take effect at the next instruction boundary after the request. When DBG\_C[TAG] = 1, a tag-type breakpoint is registered into the instruction queue and the CPU will break if/when this tag reaches the head of the instruction queue and the tagged instruction is about to be executed.

# 25.4.2.1 Hardware breakpoints

Comparators A, B, and C can be used as three traditional hardware breakpoints whether the on-chip ICE real-time capture function is required or not. To use any breakpoint or trace run capture functions set DBG\_C[DBGEN] = 1. DBG\_C[BRKEN] and DBG\_C[TAG] affect all three comparators. When DBG\_C[BRKEN] = 0, no CPU breakpoints are enabled. When DBG\_C[BRKEN] = 1, CPU breakpoints are enabled and the DBG\_C[TAG] bit determines whether the breakpoints will be tag-type or force-type

#### Functional description

breakpoints. To use comparators A and B as hardware breakpoints, set  $DBG_T = 0x81$  for tag-type breakpoints and 0x01 for force-type breakpoints. This sets up an end-type trace with trigger mode "A OR B".

Comparator C is not involved in the trigger logic for the on-chip ICE system.

# 25.4.3 Trigger selection

The DBG\_T[TRGSEL] bit is used to determine the triggering condition of the on-chip ICE system. DBG\_T[TRGSEL] applies to both trigger A and B except in the event only trigger modes. By setting the DBG\_T[TRGSEL] bit, the comparators will qualify a match with the output of opcode tracking logic. The opcode tracking logic is internal to each comparator and determines whether the CPU executed the opcode at the compare address. With the DBG\_T[TRGSEL] bit cleared a comparator match is all that is necessary for a trigger condition to be met.

### NOTE

If the DBG\_T[TRGSEL] is set, the address stored in the comparator match address registers must be an opcode address for the trigger to occur.

# 25.4.4 Trigger break control (TBC)

The TBC is the main controller for the DBG module. Its function is to decide whether data should be stored in the FIFO based on the trigger mode and the match signals from the comparator. The TBC also determines whether a request to break the CPU should occur.

The DBG\_C[TAG] bit controls whether CPU breakpoints are treated as tag-type or forcetype breakpoints. The DBG\_T[TRGSEL] bit controls whether a comparator A or B match is further qualified by opcode tracking logic. Each comparator has a separate circuit to track opcodes because the comparators could correspond to separate instructions that could be propagating through the instruction queue at the same time.

In end-type trace runs (DBG\_T[BEGIN] = 0), when the comparator registers match, including the optional R/W match, this signal goes to the CPU break logic where DBG\_C[BRKEN] determines whether a CPU break is requested and the DBG\_C[TAG] control bit determines whether the CPU break will be a tag-type or force-type breakpoint. When DBG\_T[TRGSEL] is set, the R/W qualified comparator match signal also passes through the opcode tracking logic. If/when it propagates through this logic, it will cause a

trigger to the ICE logic to begin or end capturing information into the FIFO. In the case of an end-type ( $DBG_T[BEGIN] = 0$ ) trace run, the qualified comparator signal stops the FIFO from capturing any more information.

If a CPU breakpoint is also enabled, you would want DBG\_C[TAG] and DBG\_T[TRGSEL] to agree so that the CPU break occurs at the same place in the application program as the FIFO stopped capturing information. If DBG\_T[TRGSEL] was 0 and DBG\_C[TAG] was 1 in an end-type trace run, the FIFO would stop capturing as soon as the comparator address matched, but the CPU would continue running until a TAG signal could propagate through the CPUs instruction queue, which could take a long time in the case where changes of flow caused the instruction queue to be flushed. If DBG\_T[TRGSEL] was one and DBG\_C[TAG] was zero in an end-type trace run, the CPU would break before the comparator match signal could propagate through the opcode tracking logic to end the trace run.

In begin-type trace runs (DBG\_T[BEGIN] = 1), the start of FIFO capturing is triggered by the qualified comparator signals, and the CPU breakpoint (if enabled by DBG\_C[BRKEN]=1) is triggered when the FIFO becomes full. Since this FIFO full condition does not correspond to the execution of a tagged instruction, it would not make sense to use DBG\_C[TAG] = 1 for a begin-type trace run.

# 25.4.4.1 Begin- and end-trigger

The definition of begin- and end-trigger as used in the DBG module are as follows:

- Begin-trigger: storage in FIFO occurs after the trigger and continues until 8 locations are filled.
- End-trigger: storage in FIFO occurs until the trigger with the least recent data falling out of the FIFO if more than 8 words are collected.

# 25.4.4.2 Arming the DBG module

Arming occurs by enabling the DBG module by setting the DBG\_C[DBGEN] bit and by setting the DBG\_C[ARM] bit. The DBG\_C[ARM] and DBG\_S[ARMF] bits are cleared when the trigger condition is met in end-trigger mode or when the FIFO is filled in begintrigger mode. In the case of an end-trace where DBG\_C[DBGEN] = 1 and DBG\_T[BEGIN] = 0, DBG\_C[ARM] and DBG\_S[ARMF] are cleared by any reset to end the trace run that was in progress. The DBG\_S[ARMF] bit is also cleared if DBG\_C[ARM] is written to zero or when the DBG\_C[DBGEN] bit is low. The TBC logic determines whether a trigger condition has been met based on the trigger mode and the trigger selection.

# 25.4.4.3 Trigger modes

The on-chip ICE system supports nine trigger modes. The trigger mode is used as a qualifier for either starting or ending the storing of data in the FIFO. When the match condition is met, the appropriate flag AF or BF is set in DBG\_S register. Arming the DBG module clears the DBG\_S[AF], DBG\_S[BF], and DBG\_S[CF] flags. In all trigger modes except for the event only modes change of flow addresses are stored in the FIFO. In the event only modes only the value on the data bus at the trigger event B comparator match address will be stored.

## 25.4.4.3.1 A only

In the A only trigger mode, if the match condition for A is met, the DBG\_S[AF] flag is set.

## 25.4.4.3.2 A or B

In the A or B trigger mode, if the match condition for A or B is met, the corresponding flag(s) in the DBG\_S register are set.

## 25.4.4.3.3 A then B

In the A then B trigger mode, the match condition for A must be met before the match condition for B is compared. When the match condition for A or B is met, the corresponding flag in the DBG\_S register is set.

### 25.4.4.3.4 Event only B

In the event only B trigger mode, if the match condition for B is met, the DBG\_S[BF] flag is set. The event only B trigger mode is considered a begin-trigger type and the DBG\_T[BEGIN] bit is ignored.

## 25.4.4.3.5 A then event only B

In the A then event only B trigger mode, the match condition for A must be met before the match condition for B is compared. When the match condition for A or B is met, the corresponding flag in the DBG\_S register is set. The A then event only B trigger mode is considered a begin-trigger type and the DBG\_T[BEGIN] bit is ignored.

### 25.4.4.3.6 A and B (full mode)

In the A and B trigger mode, comparator A compares to the address bus and comparator B compares to the data bus. In the A and B trigger mode, if the match condition for A and B happen on the same bus cycle, both the DBG\_S[AF] and DBG\_S[BF] flags are set. If a match condition on only A or only B happens, no flags are set.

For breakpoint tagging operation with an end-trigger type trace, only matches from comparator A will be used to determine if the Breakpoint conditions are met and comparator B matches will be ignored.

# 25.4.4.3.7 A and not B (full mode)

In the A and not B trigger mode, comparator A compares to the address bus and comparator B compares to the data bus. In the A and not B trigger mode, if the match condition for A and not B happen on the same bus cycle, both the DBG\_S[AF] and DBG\_S[BF] flags are set. If a match condition on only A or only not B occur no flags are set.

For breakpoint tagging operation with an end-trigger type trace, only matches from comparator A will be used to determine if the breakpoint conditions are met and comparator B matches will be ignored.

### 25.4.4.3.8 Inside range, $A \le address \le B$

In the inside range trigger mode, if the match condition for A and B happen on the same bus cycle, both the DBG\_S[AF] and DBG\_S[BF] flags are set. If a match condition on only A or only B occur no flags are set.

### 25.4.4.3.9 Outside range, address < A or address > B

In the outside range trigger mode, if the match condition for A or B is met, the corresponding flag in the DBGS register is set.

#### Functional description

The four control bits DBG\_T[BEGIN] and DBG\_T[TRGSEL], and DBG\_C[BRKEN] and DBG\_C[TAG], determine the basic type of debug run as shown in the following table. Some of the 16 possible combinations are not used (refer to the notes at the end of the table).

BEGIN	TRGSEL	BRKEN	TAG	Type of debug run	
0	0	0	x	Fill FIFO until trigger address (no CPU breakpoint - keep running)	
0	0	1	0	Fill FIFO until trigger address, then force CPU breakpoint	
0	0	1	1	Do not use	
0	1	0	x	Fill FIFO until trigger opcode about to execute (no CPU breakpoint - keep running)	
0	1	1	0		
0	1	1	1	Fill FIFO until trigger opcode about to execute (trigger causes CPU breakpoint)	
1	0	0	x	Start FIFO at trigger address (No CPU breakpoint - keep running)	
1	0	1	0	Start FIFO at trigger address, force CPU breakpoint when FIFO full	
1	0	1	1		
1	1	0	x	Start FIFO at trigger opcode (No CPU breakpoint - keep running)	
1	1	1	0	Start FIFO at trigger opcode, force CPU breakpoint when FIFO full	
1	1	1	1		

#### Table 25-1. Basic types of debug runs

# 25.4.5 FIFO

The FIFO is an eight word deep FIFO. In all trigger modes except for event only, the data stored in the FIFO will be change of flow addresses. In the event only trigger modes only the data bus value corresponding to the event is stored. In event only trigger modes, the high byte of the valid data from the FIFO will always read a 0x00.

# 25.4.5.1 Storing data in FIFO

In all trigger modes except for the event only modes, the address stored in the FIFO will be determined by the change of flow indicators from the core. The signal core\_cof[1] indicates the current core address is the destination address of an indirect JSR or JMP instruction, or a RTS or RTI instruction or interrupt vector and the destination address should be stored. The signal core\_cof[0] indicates that a conditional branch was taken and that the source address of the conditional branch should be stored.

# 25.4.5.2 Storing with begin-trigger

Storing with begin-trigger can be used in all trigger modes. Once the DBG module is enabled and armed in the begin-trigger mode, data is not stored in the FIFO until the trigger condition is met. Once the trigger condition is met the DBG module will remain armed until 8 words are stored in the FIFO. If the core\_cof[1] signal becomes asserted, the current address is stored in the FIFO. If the core\_cof[0] signal becomes asserted, the address registered during the previous last cycle is decremented by two and stored in the FIFO.

# 25.4.5.3 Storing with end-trigger

Storing with end-trigger cannot be used in event-only trigger modes. After the DBG module is enabled and armed in the end-trigger mode, data is stored in the FIFO until the trigger condition is met. If the core\_cof[1] signal becomes asserted, the current address is stored in the FIFO. If the core\_cof[0] signal becomes asserted, the address registered during the previous last cycle is decremented by two and stored in the FIFO. When the trigger condition is met, the DBG\_C[ARM] and DBG\_S[ARMF] will be cleared and no more data will be stored. In non-event only end-trigger modes, if the trigger is at a change of flow address the trigger event will be stored in the FIFO.

Functional description

# 25.4.5.4 Reading data from FIFO

The data stored in the FIFO can be read using BDM commands provided the DBG module is enabled and not armed (DBG\_C[DBGEN] = 1 and DBG\_C[ARM] = 0). The FIFO data is read out first-in-first-out. By reading the DBG\_CNT[CNT] bits at the end of a trace run, the number of valid words can be determined. The FIFO data is read by optionally reading the DBG\_FH register followed by the DBG\_FL register. Each time the DBG\_FL register is read, the FIFO is shifted to allow reading of the next word, however, the count does not decrement. In event-only trigger modes where the FIFO will contain only the data bus values stored, to read the FIFO only DBG\_FL needs to be accessed.

The FIFO is normally read only while  $DBG_C[ARM] = 0$  and  $DBG_S[ARMF] = 0$ , however, reading the FIFO while the DBG module is armed will return the data value in the oldest location of the FIFO and the TBC will not allow the FIFO to shift. This action could cause a valid entry to be lost because the unexpected read blocked the FIFO advance.

If the DBG module is not armed and the DBG\_FL register is read, the TBC will store the current opcode address. Through periodic reads of the DBG\_FH and DBG\_FL registers while the DBG module is not armed, host software can provide a histogram of program execution This is called profile mode.

# 25.4.6 Interrupt priority

When DBG\_T[TRGSEL] is set and the DBG module is armed to trigger on begin- or end-trigger types, a trigger is not detected in the condition where a pending interrupt occurs at the same time that a target address reaches the top of the instruction pipe. In these conditions, the pending interrupt has higher priority and code execution switches to the interrupt service routine.

When DBG\_T[TRGSEL] is clear and the DBG module is armed to trigger on end-trigger types, the trigger event is detected on a program fetch of the target address, even when an interrupt becomes pending on the same cycle. In these conditions, the pending interrupt has higher priority, the exception is processed by the core and the interrupt vector is fetched. Code execution is halted before the first instruction of the interrupt service routine is executed. In this scenario, the DBG module will have cleared DBG\_C[ARM] without having recorded the change-of-flow that occurred as part of the interrupt exception. Note that the stack will hold the return addresses and can be used to reconstruct execution flow in this scenario.

When DBG\_T[TRGSEL] is clear and the DBG module is armed to trigger on begintrigger types, the trigger event is detected on a program fetch of the target address, even when an interrupt becomes pending on the same cycle. In this scenario, the FIFO captures the change of flow event. Because the system is configured for begin-trigger, the DBG remains armed and does not break until the FIFO has been filled by subsequent change of flow events.

# 25.5 Resets

The DBG module cannot cause an MCU reset.

There are two different ways this module will respond to reset depending upon the conditions before the reset event. If the DBG module was setup for an end trace run with  $DBG_C[DBGEN] = 1$  and  $DBG_T[BEGIN] = 0$ ,  $DBG_C[ARM]$ ,  $DBG_S[ARMF]$ , and  $DBG_C[BRKEN]$  are cleared but the reset function on most DBG control and status bits is overridden so a host development system can read out the results of the trace run after the MCU has been reset. In all other cases including POR, the DBG module controls are initialized to start a begin trace run starting from when the reset vector is fetched. The conditions for the default begin trace run are:

- DBG\_CAX = 0x00, DBG\_CAH=0xFF, DBG\_CAL=0xFE so comparator A is set to match when the 16-bit CPU address 0xFFFE appears during the reset vector fetch
- $DBG_C = 0xC0$  to enable and arm the DBG module
- DBG\_T = 0x40 to select a force-type trigger, a BEGIN trigger, and A-only trigger mode

#### Resets
